Syntactic Simplification for Machine Translation

A Project submitted as part of a programme of study for the award of
MA Natural Language Processing & Human Language Technology

Supervisors:

Richard Evans

Sandrine Fuentes

Sylviane Cardey-Greenfield

May 2013

Abstract

This research presents a new rule-based Syntactic Simplification system for the Spanish language. The system basically consists of splitting complex sentences into several simple ones preserving its original meaning. It is envisioned to be a preprocessing tool for other Natural Language Processing applications such as Text Summarization, Information Extraction, Parsing and Machine Translation. This research includes a comparison between direct Machine Translation and Machine Translation using the Syntactic Simplification prior to the translation. According to the evaluation, the application of the syntactic rules proposed clearly improves Machine Translation from Spanish to far target languages such as Korean and Chinese.

A parallel corpus of Spanish original and simplified texts has been manually built for this research. The corpus has been validated by native Spanish speakers. The results extracted from the validation suggest that the meaning of the original and simplified sentences is preserved without damaging its grammaticality. In addition, an experiment was carried out among two groups of Spanish learners comparing their reading comprehension of original and simplified texts. Their answers show a null correlation between simplification and text comprehension.

The automatic Syntactic Simplification system has also been intrinsically evaluated on the simplification of complex sentences containing two conjugated verbs. The results are quite promising as more than 90% of the evaluated sentences were positively handled by the system.

Keywords: Text Simplification, Syntactic Simplification, Natural Language Processing, Spanish, Machine Translation.

Resumen

Esta investigación presenta un nuevo sistema de Simplificación Sintáctica para el español. El sistema consiste básicamente en dividir una oración compleja en varias simples preservando el significado original. El sistema se ha desarrollado con el objetivo de servir como preprocesador de otras aplicaciones del Procesamiento del Lenguaje Natural como el Resumen Automático de Textos, la Extracción de Información, el Análisis Sintáctico o la Traducción Automática. Según las evaluaciones llevadas a cabo en esta investigación, la Simplificación Sintáctica propuesta mejora la traducción automática del español a lenguas lejanas como el coreano o el chino.

Asimismo, se ha construido un corpus paralelo español-español simplificado para esta investigación. El corpus ha sido después validado por españoles nativos. Los resultados extraídos de la validación sugieren que el significado de las oraciones originales y las simplificadas es prácticamente idéntico. Además, se ha llevado a cabo un experimento entre dos grupos estudiantes de español para comparar su compresión lectora de textos originales y simplificados. Sus respuestas muestran una nula correlación entre la simplificación y la comprensión de textos.

El sistema automático de Simplificación Sintáctica que ha sido desarrollado en esta investigación ha sido también evaluado intrínsecamente en la simplificación de oraciones complejas con dos verbos conjugados. Los resultados son prometedores ya que más del 90% de las oraciones evaluadas fueron positivamente simplificadas por el sistema.

Résumé

Ce travail présente un nouveau système de Simplification Syntactique pour la langue espagnole. Le système, basé en règles, essaye de diviser des phrases complexes en d'autres plus simples mais en conservant le sens de la phrase originale. Le système est développé en tant qu'outil de prétraitement pour d'autres applications du Traitement Automatique de Langues comme le résumé automatique de textes, l'extraction d'information, l'analyse syntaxique ou la traduction automatique. Les résultats montrent que la Simplification Syntactique proposée améliore la traduction automatique de l'espagnol vers des langues très éloignées comme le coréen ou le chinois.

Un corpus parallèle simplifié espagnol-espagnol a été construit pour cette recherche. Ce corpus a été validé pour des espagnols natifs. Selon les résultats obtenus à partir de cette validation, la signification des phrases originales est préservée après la simplification. Cette recherche a également envisagé une étude avec des étudiants d'espagnol pour comparer la compréhension des textes originaux et simplifiés. Les réponses des étudiants présentent une nulle corrélation entre la simplification et la compréhension.

Un système automatique de Simplification Syntactique a été aussi développé et évalué concernant des phrases complexes de deux verbes conjugués. Les résultats sont encourageants puisque plus de 90% des phrases évaluées ont été simplifiées d'une façon positive par le système.

Acknowledgements

Firstly I would like to give a big thank you to Yunseo and Ángela, whose help and support was really important to me. Without them, this work would not have been possible.

Special thanks to the translators Prof. Zheng Quan Zhang and Mi Kyung Lee, whose generous and perfect translations from Spanish to Chinese and Korean were essential in the whole evaluation process. I would also like to thank all the other Chinese and Korean collaborators who helped me with the evaluation.

I am also grateful for the help from the collaborators in the validation of the corpus and from the students and professors of *Facultad de Traducción e Interpretación (Universidad de Granada)* who agreed to collaborate in one of the experiments of the research.

I would like to acknowledge my supervisors: Prof. Sandrine Fuentes from *Universitat Autònoma de Barcelona*; Prof. Richard Evans from the *University of Wolverhampton*; and Prof. Sylviane Cardy-Greenfield from *Université Franche-Comté*. I would also like to thank to all the people who helped me in some way during my stay in the three universities.

This research was partially supported by the European Commission, Education & Training, Erasmus Mundus: EMMC 2008-0083, Erasmus Mundus Masters in NLP & HLT programme.

Last but not least, thank you to Obra Social “La Caixa”, which supported this masters by a “La Caixa” grant for master studies in Spain.

1. Introduction

“Text Simplification is a Natural Language Processing task that aims to rewrite sentences to reduce their syntactic or lexical complexity while preserving their meaning”
(Siddharthan 2002: 1)

Text Simplification (TS) is a Natural Language Processing (NLP) task consisting of reducing the complexity of a sentence in order to make it simpler, but without changing the general meaning of it. Depending on the purpose of the simplification, there are two main types: Lexical Simplification (LS) and Syntactic Simplification (SS). This research focuses on the syntactic level. The syntactic simplifications considered are basically based on splitting a complex sentence into several simpler ones without damaging its original meaning.

The motivations for Text Simplification are basically divided in two main groups. The first one is the one which uses TS in order to make a text accessible for certain people with problems in reading complex structures. Amongst these people, we can find language learners and people suffering some kind of language disability such as aphasia. People suffering this disorder become unable to read and understand some structures and TS attempts to modify the text so that complex structures disappear. This research includes an evaluation of the system regarding this application but, more specifically, for foreigners learning Spanish.

The second main group within TS includes the systems aiming to improve other NLP applications. The rules from this group differ in some way from the rules proposed to make a text more understandable for certain groups of the population. Even though there is an evaluation within language learners included in this research, the SS proposed in this thesis is mainly envisioned to be used as a preprocessing tool for other NLP

applications. The applications which may be improved from this approach are Text Summarization, Information Extraction, parsing or Machine Translation (MT):

-Text Summarization: The idea for the TS in Text Summarization is to reduce the information extracted by each sentence, keeping just the relevant one. Since Text Summarization is sometimes based on the information extracted from different sentences, having the information better divided in sentences might be extremely useful for the task (Chandrasekar et al., 1996; Siddharthan, 2002).

-Information Extraction: As far as Information Extraction is concerned, automatic systems usually work better when the complexity of a sentence is low. They are usually based on some kind of automatic parsers in order to extract the relevant information. Example (1) shows how TS may help store different types of information inside a complex sentence into several simpler sentences.

- (1) a. *Obama, who was born in Hawaii, is currently the US president.*
(One sentence, two statements)
- b. *– Obama was born in Hawaii.* (One sentence, one statement)
– Obama is currently the US president. (One sentence, one statement)

-Parsing: The goal of TS in parsing is due to the improvement of performance if given a short sentence as input (Siddharthan, 2002). Longer sentences give more cases of ambiguity, so that TS aims to reduce the length of the sentences while preserving the meaning as much as possible.

-Machine Translation: It will be the NLP application evaluated on this research. The possible benefits of using TS for Machine Translation will be explained in more detail in the next Subchapter.

1.1 Text Simplification for Machine Translation

One of the evaluations of the SS system carried out on this research will be extrinsic and it will be done regarding the improvement of some MT systems taking Spanish as source language. The target languages taken into account in this research will be Chinese and Korean. The distant languages (such as Spanish and either Chinese or Korean) and long sentences are nowadays two of the main drawbacks of MT, so it would be quite useful to have a tool improving current MT systems on this matter regardless of the target language. It will be especially relevant for MT systems which are not largely developed, as we can observe in Example (2), where Spanish-Korean Google Translate has been used as MT system.

- (2) a. *La policía, que últimamente ha sido duramente criticada, ha detenido a dos secuestreadores.*
[Police forces, who have been very criticized lately, have arrested two kidnappers]

Google Translate: 무겁게 최근 비판을 받아왔다 경찰은 두 납치범을 체포했다.
[Somebody (unknown) has been heavily criticized lately police have arrested two kidnappers.]

- b. – *La policía últimamente ha sido duramente criticada.*

Google Translate: 경찰은 무겁게 최근 비판을 받아왔다.
[Police have been heavily criticized lately.]

- *La policía ha detenido a dos secuestreadores.*

Google Translate: 경찰은 두 납치범을 검거했다. [Police have arrested two kidnappers.]

The output sentence given by direct MT is not quite grammatical in the Korean language and there are several issued damaging the original meaning of the Spanish sentences. The output sentences obtained by using SS prior to the Google Translate are grammatical and accurate translations from the original Spanish sentence.

SS is therefore used in order to solve some of the MT problems handling complex sentences. Firstly, as we have seen in the previous chapter, parsing could be benefited by this SS system. Since parsing is usually an essential tool to preprocess an input sentence, especially for rule-based MT approaches, the MT system would be directly improved. Secondly, Rule-based MT systems tend to backfire when the complexity of a given sentence is quite high and work better when this complexity is low. Therefore a preprocessing tool to reduce the complexity of a sentence such us a SS system could be quite appropriate. The split of the given sentence into several simple ones may lead to a better performance of these MT systems.

As far as Statistical Machine Translation (SMT) is concerned, the length of a sentence is inversely proportional to the accuracy of the system. This is not only due to the increasing number of possible alignments in long sentences, but also to the reliability of the language model, which mainly relies on n-grams found on a monolingual text. The combination of these two factors makes a SMT system be quite more reliable in short and medium size sentences.

Last but not least, it is important to notice that SS is carried out just on the source language no matter the target language. This kind of monolingual approach is quite requested nowadays because of a purely mathematical reason. The total number of language pairs (and consequently the MT systems to be developed) is much larger than the total number of languages in the world, as we can appreciate in the Table 1. The difference is from order n^2 , being n the total number of languages. That is the reason why the MT tasks tend to be divided as much as possible and focus on source and target language separately, i.e., monolingual tasks are computationally less expensive than working on specific MT systems directly.

Table 1: Relation between number of languages and language pairs

Number of languages	N	n
Number of language pairs	$n*(n-1)/2$	$O(n^2)$
Number of MT systems	$n*(n-1)$	$O(n^2)$

Monolingual tasks other than using a reliable language model could be applied on the target language too. If necessary, specific target language models could be used to improve the fluency of simplified sentences translations, which will be often split sentences from the original one. This could be done by packing the information of the group of output sentences produced by the simplification into a single complex one, taking the inverse way of the SS carried out in the source language.

1.2 Plan and goals of the project

This project aims to create an automatic syntactic simplification system which is envisioned to be used as a preprocessing tool for other NLP applications. The research includes a first version of this automatic system for the Spanish language which applies on sentences with two conjugated verbs at this stage. By conjugated verbs, we are referring to the verbs on the Spanish language which need a subject to be completed.

To fulfill this goal, a small parallel corpus of Spanish original and simplified sentences is also provided. This corpus has been developed by following all the desirable rules for the simplification. The corpus will be useful in order to be used as an analysis tool prior to the creation of an automatic system. It has also been used for several evaluation tasks in this research. Simplified sentences have been used as Gold Standard for the SS system and as reference to evaluate the benefits of this approach.

This project, apart from the main goal of improving a MT system, will also study the effect of simplification on foreigners learning Spanish. This extrinsic evaluation will therefore concern to the readability and possible improvements on the understanding of a text by this part of the population which do not have a perfect domination of the language. An experiment has been carried out with intermediate and advance Spanish

learners in order to find out whether this approach makes the text more accessible to certain ranges of the population or not.

To conclude with, this research will have as main purpose to evaluate the improvements of a MT system by using this SS approach. The way to implement it and some preliminary thoughts about the improvement of the MT system have already been explained in the previous Subchapter. It will also be evaluated taking the Spanish language as the source language and far languages as the target language. The target languages considered in this research will be Korean and Chinese.

1.3 Research outline

This project is organized in seven chapters. Chapter 2 shows previous researches related to Text Simplification and Machine Translation. Subchapter 2.1 includes the first researches about TS and Subchapter 2.2 shows an important state of the art TS system developed by Siddharthan. Some corpus-based TS approached are commented on whereas Subchapter 2.4 focuses on TS for the Spanish language. Finally, Subchapter 2.5 treats some problems of MT and Subchapter 2.6 shows works improving MT by using controlled languages.

Chapter 3 explains the methodology followed along this research including details of the SS splitting rules considered (Subchapter 3.1) and the final decisions taken at the last stage of the simplification, the regeneration (Subchapter 3.2).

Chapter 4 introduces the Spanish parallel corpus of original and syntactically simplified sentences created by following the rules explained in Chapter 3 (Subchapter 4.1) and its validation (Subchapter 4.2).

Chapter 5 shows the development and architecture of the automatic SS system by applying the rules presented in the methodology. It is divided in three stages: the analysis

stage (Subchapter 5.1), the transformation stage (Subchapter 5.2) and the regeneration stage (Subchapter 5.3).

Chapter 6 includes both the extrinsic and intrinsic evaluations of the system. As for the extrinsic evaluations will be handled on Subchapters 6.1 and 6.2 while the intrinsic evaluation of the system will be done on Subchapter 6.3. Subchapter 6.1 evaluates one of the main applications of this system, Machine Translation. Section 6.1.1 will consider Korean as the target language while Section 6.1.1 will take Chinese as the target language. The other extrinsic evaluation about improving the comprehensibility of a text for foreigners studying Spanish is handled on Subchapter 6.2. Finally, Subchapter 6.3 includes the results concerning the evaluation of the automatic SS system.

To end with, Chapter 7 gives the conclusions of the work (Subchapter 7.1) and addresses some possible directions for further research on the subject (Subchapter 7.2)

2. Text Simplification and Machine Translation: Literature review

Different researches about Text Simplification (TS) have been carried out in recent years. Although it has been referred the potential of using TS for MT purposes (Chandrasekar et al., 1996; Siddharthan, 2002 and 2004), the effectiveness of this approach has not been proved yet. TS has also been used for other Natural Language Processing (NLP) applications such as Information Extraction (Klebanov et al., 2004; Evans, 2011). However, it has been mainly used for human with reading problems or adults learning a language so far (Petersen and Ostendorf, 2007; Aluísio et al., 2008; Specia et al., 2009; Specia, 2010; Bott and Saggion, 2011a, 2011b). Therefore, most of the simplification rules used on these approaches follow this direction.

This chapter starts with the presentation of the first attempts on TS (Subchapter 2.1). This is followed by an important state of the art TS system (Subchapter 2.2) whose architecture has been used as a model for this research. More recently, some machine learning approaches have been developed. These approaches are presented in Subchapter 2.3.

As far as Spanish TS is concerned (Subchapter 2.4), the need of a Spanish parallel corpus with original and simplified sentences has been addressed in previous papers (Bott and Saggion, 2011a, 2011b). Therefore the creation of a manually aligned corpus would be useful not only to build the SS system for this project, but also for future researches on this area. However, like previous attempts on TS, Spanish TS has been focused on improving the readability and understandability of texts but not as a preprocessing tool for other NLP applications.

In order to build a reliable TS system helpful for MT, it would be essential to create some specific simplification rules. That is the main reason why these previous researches have not been able to check whether MT could be improved with TS or not. There are other researches handling the problems of MT for the natural language

(Subchapter 2.5) and proposing some alternatives such as the controlled languages (Subchapter 2.6). Controlled languages are artificially created languages with a low complexity which have been proved to be quite reliable for MT purposes. This could suggest an improvement of MT in natural languages if a proper TS system is used as a preprocessing tool.

2.1 First steps in Text Simplification

Chandrasekar et al. (1996) was the first serious attempt in order to create a general architecture for a TS system. In the research, they comment the usefulness of the TS for a wide variety of applications. The main applications have been explained in Subchapter 1.1. Apart from helping NLP applications such as MT, parsing and Text Summarization, Chandrasekar et al. (1996) introduce the possibility that TS could help Information Retrieval. The reason is quite simple, TS reduces the length of the sentences, so the query could be solved in a more appropriate way, as all the information searched could be found in a simple sentence instead of a long sentence. Not only are NLP applications addressed as possible beneficiaries of the TS, but also TS could make the text clear and easier to understand. This could be particularly useful for manuals when creating an artificial language is not such a difficult task. TS could be used as a preliminary step in order to create this artificial constrained language like controlled languages, which will be deeply studied in Subchapter 2.6. Nevertheless, the research was focused on improving the performance of a parser, which consequently would be beneficial for the other applications.

Regarding this task of improving a parser, the main problem was to reduce the complex syntactic structures that we can find in long sentences. This was achieved by opportunistically splitting the complex sentences into two or more simple ones. To do so, as a first step it was necessary to decide whether the sentence is a candidate to be split or

not. At the beginning of their research there is an example (Chandrasekar et al., 1996: 1) showing how the system works – see Example (3).

- (3) a. *The embattled Major government survived a crucial vote on coal pits closure as its last-minute concessions curbed the extent of Tory revolt over an issue that generated unusual heat in the House of Commons and brought the miners to London streets.*
- b. *The embattled Major government survived a crucial vote on coal pits closure. Its last-minute concessions curbed the extent of Tory revolt over the coal-mine issue. This issue generated unusual heat in the House of Commons. It also brought the miners to London streets.*

However, there is a lack of a general explanation of how the system decides the simplifications and a general overview of the main SS rules carried out. This is an important lack as we cannot even guess the real power of the system. They state that the starting point is to find a possible articulation point. As an articulation point, punctuation marks, coordinating and subordinating conjunctions, beginning and end of a phrase, and relative pronouns are included. It is also explained that these articulations points could be modified or augmented depending on the domain. Therefore they implicitly claim that their TS system could work more accurately in a domain-specific framework. They apply their system on a corpus of news stories. However, there is not a clear experiment of the system within the domain so it becomes hardly difficult to keep the same direction of research. It would have also been quite appropriate to have studied what to do where a parser fails to recognize these punctuation marks, or even correctly recognizing them, what to do if the punctuation mark is not exactly adjusted to the structure searched. Therefore a general set of patterns and rules should have been commented in order to help further research.

There are two methods carried out in Chandrasekar et al. (1996): the first one is based on a Finite State Grammar (FSG) and the second one is based on syntactic

information given by a dependency representation. FSG is used in order to obtain the chunks of the sentences, which are the basis of this first method. From there, a set of simplification rules based on those chunks was decided. This set of simplification rules are built manually and just general patterns are taken into consideration. This is one of the main problems of this system. As the rules are not deeply developed, the system fails to simplify a wide range of sentences. This system was evaluated in a corpus of news stories of 224 sentences. The evaluation gave as a result several weaknesses of the system. Apart from having a small and not very complex set of rules, they pointed out that it is necessary to rely on a richer syntactic structure in order to obtain better results.

The second method attempts to solve these problems of the first FSG approach. It is based on parsing and particularly, on the dependency information of the sentence. The dependency representation is given by Lexicalized Tree Adjoining Grammar (LTAG). In this case, a much richer syntactical representation is taken into consideration, the dependency trees. The identification of a sentence candidate to be simplified is also taken from the trees, identifying coordination, relative clauses and other parts previously selected.

The evaluation was made in a corpus of news. However, it is not clear how this was carried out. It is claimed that the Dependency-based Model clearly outperforms the FSG. This is due to the much richer syntactic information captured by the first one, while the FSG just relies on chunking and a not quite big set of rules. It would have been interesting to have seen the exact rules to be really able to compare the two methods, as the FSG could perform better if higher developed. In this case, the Dependency-based Model was expected to work better as it takes advantage of a more complete parser. The evaluation gave also promising results for some specific structures. These successful structures are relative clauses and appositives, the latter getting a 100% of accuracy in the corpus. A new direction for further research is suggested, as several problems related to the discourse are addressed.

2.2 Siddharthan's Text Simplification architecture

Siddharthan (2002) proposes a new architecture for a TS system. It follows the work of Chandrasekar et al. (1996) but introducing quite remarkable improvements. He keeps the same line and gives similar applications to his TS system, yet without any external evaluation to verify it. The first difference that we could notice from the previous work is the introduction of a new stage on the TS process: regeneration. This is the main improvement of this research and where Siddharthan tries to focus on. The discourse level problems raised by Chandrasekar et al. (1996) are partially solved by this new stage in the system. The new architecture is then based in three stages: analysis, transformation and regeneration. LS is also included on his system. More specifically, he suggests two ways for LS: paraphrasing and synonym substitution. The paraphrasing involves dictionary lookup and the substitution consists of replacing a word for a simpler synonym. Both could be a useful tool to solve some kind of ambiguity within the phrase. The full architecture is summarized in the Figure 1, taken from his own work.

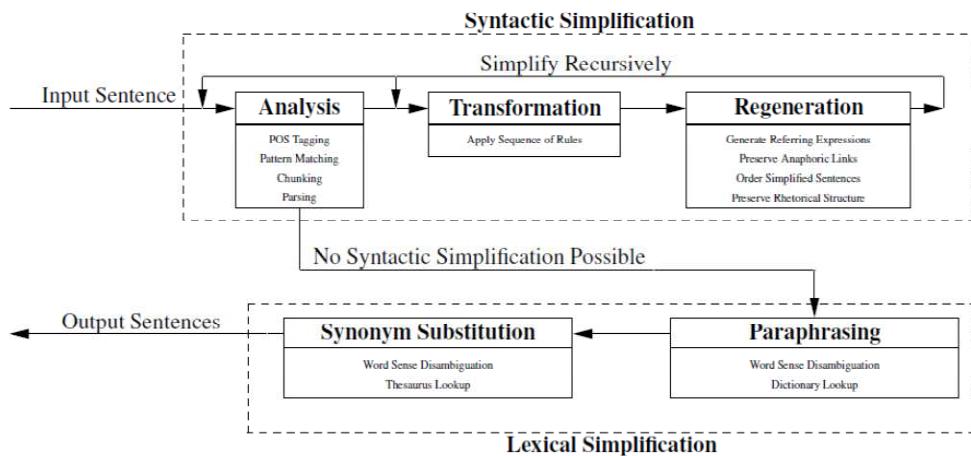

Figure 1: Architecture of a Text Simplification system (Siddharthan, 2002: 3)

As far as SS is concerned, Siddharthan (2002) considered several syntactic phenomena such us relative clauses, adverbial clauses, coordinated clauses, subordinated clauses, correlated clauses, participial phrases, appositive phrases and passive voice. He gave specific examples of how the system works for each of them. From them we can appreciate that he keeps quite similar transformation to the previous Chandrasekar et al. (1996). Afterwards, he analyzes and evaluates each stage separately, giving more emphasis to the new regeneration stage.

The analysis stage relies on shallow parsers such as Part of Speech (PoS) tagging and chunking. This is due to the slow analysis given by full parsers and the mistakes that these also produce in long and complex sentences, which are the ones pretended to be simplified. However, he uses different techniques regarding the syntactic phenomenon present in the sentence. For instance, for relative clauses, the use of WordNet and machine learning are suggested. The evaluation shows that his system can identifies correctly relative clauses with accuracy higher than 95%. In addition, the mistakes of in the system are correctly detected and it is present in approximately 25% of the cases of the corpus, whereas the remaining 75% sentences get an accuracy of almost 100%.

The transformation stage is just a set of manually created rules which are directly applied as indicated in Figure 2 for the transformation of a relative clause.

$$\begin{array}{c}
 V\ W:\text{NP}_{ant},\ \text{Rel_Clause}(X:\text{Rel_Pr}\ Y),\ Z. \\
 \downarrow \\
 V\ W\ Z.\ W\ Y.
 \end{array}$$

Figure 2: Transformation stage (Siddharthan, 2002: 5)

Finally, he gives a deep explanation about the last stage, regeneration. There are two main reasons why he creates this new stage. The first is purely stylistic, which is essential to keep some readability in the text, and the second one is to preserve some anaphoric links. This second reason is in some cases essential, otherwise the simplified sentence could present a quite different meaning from the original one. It is necessary to

create an anaphora resolution procedure in order to preserve the anaphoric links. The research uses an algorithm which successfully solves many problematic cases. The evaluation gives 81% of correct results, 13% of acceptable results and a 7% of wrong results. These 7% of the mistakes are mainly due to the incorrect analysis in complicate structures. So this lead to a huge improvement by this regeneration stage and directions of how to improve the process are in many cases external to this stage. The order of the simplified sentences is also evaluated giving quite good results. 100% of the cases have an acceptable order. From them, just 8% could have had a better order than the one given by the system.

Although there are different evaluations for each different stage, there is a lack of an evaluation of a general evaluation of the system, and even some extrinsic evaluations. As SS is done as a tool to be used prior to other applications, it would have been quite appropriate to assess the best external applications of this system and an evaluation of these applications.

Siddharthan (2011) compares two different approaches for the regeneration stage using dependency representation given by the Stanford parsers. The goal is to find a suitable approach to deal with one of the main problems in building a TS system: the reliability of parsers. Therefore the robustness of two TS systems towards parsing errors is evaluated. In the end, he concludes that the system becomes more robust if making use of the word order and morphology of the original sentence.

2.3 *Corpus-based Text Simplification*

Several rule-based systems were created after Siddharthan's work. Some of them already gave some external evaluation depending on the purpose of the system (Petersen and Ostendorf, 2007; Evans, 2011). There are also works addressing the need of a parallel corpus of original and simplified sentences (Petersen and Ostendorf, 2007;

Aluísio et al., 2008; Specia et al., 2009; Specia, 2010). The corpus, apart from potentially being used to develop a *Machine Learning* algorithm, would be useful to carry out a deeper analysis of the task leading to some new ideas or improvements of rule-based TS systems.

Specia et al. (2009) followed this direction and worked on building a Brazilian Portuguese parallel corpus of original and simplified sentences with both lexical and syntactic simplifications. The main goal of the corpus is to help people with low level of literacy or some other cognitive disabilities. In the corpus, they even separate two kinds of simplification changes: natural and strong. This could be particularly useful as the purposes for the TS could be very different, so that depending on the nature of the goal of the system, either strong or natural will be more appropriate than the other. The corpus consists of 104 texts from a corpus of news, which were simplified by a linguist expert in TS. This work includes as well a Simplification Annotation Editor, which could be used in future similar works for other corpus of different languages.

Specia (2010) experimented afterwards with a quite simple corpus-based TS approach. The goal of this system is the same as in Specia et al. (2009), for people with some problems at reading. She basically used a Statistical Machine Translation (SMT) method to deal with the TS problem and check the results. The SMT was carried out without making many changes, so that the approach could be easily improved by adapting the framework to the particular TS problem. The corpus used was taken from two Brazilian newspapers. The corpus was manually annotated by native Brazilian speakers. In such annotation, the kind of the simplification was also annotated on the simplified sentence. The operations taken into consideration were eleven, including LS, SS and non-simplification in some cases. One of the operations was called strong rewriting and it includes any other kind of simplification not covered by any other.

The SMT framework was a current state of the art system. Moses was used in this case. The features used in this new approach included the language model, phrase translation model, word penalty, distortion limit and a model covering the reordering of

the lexical items. The training to decide the weights of the features was given by the Minimum Error Training, as explained in Och (2003).

The evaluation was performed in two different ways: automatic with scores such us BLEU and NIST, and manual evaluation. The automatic evaluation gave a score of BLEU = 0.6075 and NIST = 9.6244. A BLEU score of 0.6 means that the translation quality is not quite bad, so these results, though not perfect, are quite promising for future similar experiments. The manual evaluation was made in just 20 segments from the total test corpus. It was done by comparing the target sentences given by the system with a Gold Standard created by a human. Fluency, adequacy and simplifications performed were the characteristics measured. The scores were 1 to 3, being 1 none of the simplifications was performed and 3 all the simplifications expected were performed. The results were that fluency got a 2.5, adequacy 2.5 and simplification 2.3, which seem not bad at all at a first glance. However, a deeper analysis stated that most of the SS were not well captured, as it hardly ever was performed by the system. Therefore this method should be highly improved in order to perform some SS tasks. The most promising results were given by LS, which let us think that this method could be a better approach for this task. The future work should be focused on building a larger parallel corpus as this usually easily improves the performance of a SMT system. This contained just around 4000 sentences pairs, which is not a high number compared to the normal amount of sentence pairs for a SMT system. Furthermore, it will be necessary to adapt the SMT framework in order to make it more suitable for the TS framework, especially for SS, where it did not perform quite well.

2.4 Spanish Text Simplification

Bott and Saggion (2011a) studies the problem of TS for the Spanish language. The goal of Bott and Saggion (2011a) is to create a text easy to read for people with learning disabilities, so it differs in this point from the main goal of this research. It is a preliminary study where they analyze a corpus of news and the respective simplified one. They address the need of getting a parallel corpus in order to be able to use it for the creation of a reliable TS system.

The corpus was firstly parsed and then aligned (the original text with the simplified one). The alignment was carried out automatically and it attempts to be a tool for future creation of parallel corpus of original and simplified sentences. This could be quite useful, as in Spanish it is possible to find these parallel corpora but it is impossible to find them manually aligned. With the help of this system, obtaining a parallel corpus would be a task much easier than in the present. The method is carried out by using TF*IDF measures and sentence similarity, where the last one was proved to perform better for this particular task.

The operations considered for the research are the usual ones, present in Siddharthan (2002): change (usually for LS), delete, split... In Bott et al. (2011a), it is highlighted the need of keeping a track of the changes made throughout the corpus. This could be automatically, by creating a hand-crafted set of rules or even with an opportunistic combination of both. It is also addressed the need of having a reliable anaphora resolution system, as many of the operations could be done just by recognizing some anaphoric components within the sentence or sentences. They also emphasize on the need of getting a larger parallel corpus in order to apply machine learning techniques, especially for SS. To conclude, it is addressed the need of getting a global evaluation metric for TS, which is actually one of the main problem of this topic. They indicate some ways to do so but indicating the actual difficulty to solve this. This should be one of

the main directions of research of the near future, as it is necessary to keep a track of the improvements in this area.

Bott et al. (2011b) follows their last paper and explain in detail an algorithm to align a parallel corpus of news and their simplified ones at a sentence level. As there is not training data for task (there is no manually aligned parallel corpus), they rely on unsupervised learning. The alignment is done applying a Hidden Markov Model given by two starting points: simplified sentences and original ones usually share similar words and the order does not change in many cases. Using these two intuitions they build the machine learning algorithm to find the alignments within the corpus. The results suggest that this approach has improved previous alignments algorithms at a sentence level, though it is not directly comparable as this algorithm attempts to solve a very specific problem whereas the previous ones had a different goal. The system that they use to compare to is the given in Nelken and Shieber (2006), relying on TF*IDF scores and supervised learning. They took advantage of a training corpus that Bott et al. (2011b) could not get.

However, as explained before, this method may be modified regarding the transformations taken into consideration. The transformation from an original text to a text easy to read as in Bott et al. (2011b) will differ from the SS considered in this research. The difference between an original sentence and a simplified sentence affected by SS for MT will share much more similar words than in Bott et al. (2011b). This will lead to some modifications in the intuitions which will be relevant, even though this algorithm could be used as a starting point.

Drndarević et al. (2013) presents a two-component (syntactic and lexical) automatic text simplification system for the Spanish language in order to make the text easier to read for people with cognitive disabilities. The system managed to get simpler sentences without seriously damaging their grammaticality and preservation of meaning with the original sentences. However, they do not propose any solution to the parsers errors, which caused most of the errors found in the system.

2.5 Problems in Machine Translation

Cardey et al. (2004) addressed the problem for the MT between an Indo-European language such as French and two languages belonging to a far language such us Chinese and Arabic. The MT method considered in the research is transfer, though the conclusions stated here could be extended to other rule-based approaches. A conclusion taken from the article is that semantics of linguistic units is a very special issue which should be treated with a special care. Another main conclusion is that many of the issues concerning a pair of language studied separately for each different language pair, which makes these MT systems really language-independent. This is a problem as many pairs of minority languages will not receive the needed attentions to solve all these kinds of problems. SS could partially solve this problem, as it could be seen as an attempt to reduce the complexity of the source language. Although the complexity from a language pair could differ from another language pair with the same source language, a reduction on the complexity of the source language could always lead to an improvement on the translation quality.

This could be also extensible for SMT. SMT also improves the quality while translating simple sentences (Koehn, 2010). SMT tends to backfire when the source sentence is long and have several verb phrases, no matter the target language. SS consists mainly of reducing the complexity of a complex sentence, usually by splitting the sentence into several simple ones. So an appropriate SS system created with the goal of improving a MT system for a specific source language could be of great help. Considering a source language with a SS system, it would improve the translation quality of both rule-based and statistical MT for no matter what target language.

2.6 Controlled Languages and Machine Translation

The problems of MT often come, apart from the length of the sentence, from the ambiguity that such sentence could have. MT systems should deal with this problem, which is one of the main ones for every system. Even deeply treated, ambiguity is really complicate to be totally solved in order to create a high quality MT system. That is one of the main reasons why controlled languages were developed (Kaji, 1999; Mitamura, 1999; Cardey, 2011).

Controlled languages are artificially created subset of the natural language where the ambiguity is eliminated and complexity is reduced. This obviously improves MT and it is especially useful where used for different target languages. In controlled languages, vocabulary, grammar and even style are restricted. The restriction in vocabulary aims to eliminate the lexical ambiguity within the sentence. The words will no longer polysemous, as just a meaning from a specific part of speech will be kept. The grammar restrictions have several goals. The first one is to reduce the syntactic ambiguity of the sentence. The relation within the phrase should be clear so some constructions and problematic orders are avoided. Another goal is to keep the simplicity of the sentence. Therefore there should be a limit of words in the sentences and coordinated and subordinated sentences are in some cases reduced. The restrictions on the style are on the same line with the grammar restriction. The punctuation and the structures used should be clear and easier to process for a MT system.

Although controlled languages belong to natural language, it is artificially created. This is one of the main problems of the controlled language. They need to be created and people using this language should know all the restrictions in order to be able to use it. As explained in Mitamura (1999), this is not an easy task because usually there is a big restriction in both grammar and vocabulary, so it should be deeply studied before using it. This is the point where TS could be quite useful. TS treats natural language and aims to reduce the complexity and ambiguity of the sentences. LS could be compared to the

vocabulary restriction of the controlled languages and SS the grammar restriction. On this way, TS could be seen as a preliminary step to the MT for controlled languages. In Figure 3, we can appreciate how TS could be integrated in the MT process as preprocessing tool on the source language.

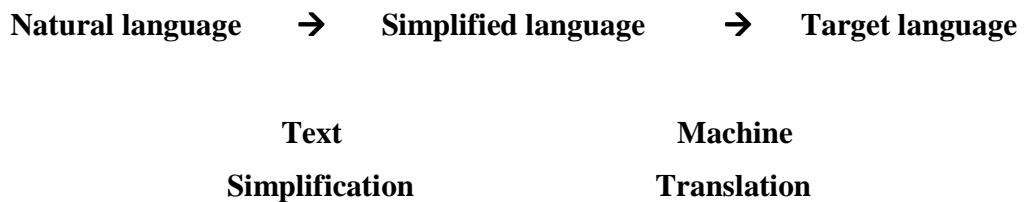

Figure 3: Integration of Text Simplification in a Machine Translation system

As controlled languages have been proved to be a useful approach for MT (especially for systems which include a source language and several target ones), TS could be used as a tool to reach the desirable controlled language. TS could be used to as a preprocessing tool on the whole MT process. Temnikova (2012) shows how the post edition by a human translator becomes an easier task by applying TS prior to the MT. This research will evaluate the output given by the MT directly and compared it with the output given by using SS. It is obviously not an easy task to build a TS which could take natural language as a starting point and give a controlled language as result. Some of the ambiguity and complexity of the source sentence will not be solved as completely as with controlled language but the advantage of starting from natural language could be worth trying.

3. Methodology

As it has been commented in previous chapters, the main goal of this project is the creation of an automatic Syntactic Simplification system to be applied on other NLP applications such as Machine Translation (evaluated in Chapter 6), Information Extraction, Information Retrieval or Parsing. Therefore the rules have been built taking into consideration these two premises: rules easily implementable on an automatic system and useful for these NLP applications. The rules are basically based on splitting complex sentences into several simpler sentences preserving its original meaning. All the rules summarized on this chapter have been decided by following this premise.

This Chapter will therefore explain the basis of this SS approach. Chapter 3.1 presents the general splitting rules considered for this research and Subchapter 3.2 handles the regeneration stage, which is a more complex stage of the syntactic simplification process. The rules presented in this Chapter will be the ones used in Chapter 4 for the creation of a parallel corpus of original and simplified sentences (Camacho Collados, 2013). The automatic SS system presented in Chapter 5 will be also based on these transformations.

3.1 Syntactic simplification splitting rules

To begin with, the first condition to split a sentence is the number of conjugated verbs. The sentences which are to be simplified must have at least two conjugated verbs. However, not all this kind of sentences will be simplified, as there are some kind of structures which do not allow splitting and preservation of meaning simultaneously. It is also important to notice that in most sentences there are different types of structures to be

simplified simultaneously, which makes the task harder. The main structures (one per sentence in the following examples¹) allowing the simplification are summarized below:

➤ **Coordination:** The original sentence is split on the position of the coordination nexus or articulation point as called by Chandrasekar et al. (1996). It is sometimes recommendable to repeat some noun phrases in order to improve the understandability and a best processing by other NLP applications. Example (4) shows an illustrative example of how the simplification is handled on a coordination structure.

- (4) a. *Fishes swim in the sea and butterflies fly in the sky.*
b. – *Fishes swim in the sea.*
– *Butterflies fly in the sky.*

➤ **Subordination:** The simplification is done by taking into consideration the subordination type. It is also worth noticing that there certain kinds of subordination which do not allow a syntactic simplification without change of meaning. Therefore every case has been studied separately and some cases of subordination and its simplification are the following: some kinds of relative clauses; cause and effect; indirect speech to direct speech...

• **Non-restrictive relative clauses:** This kind of structure is split without adding any other element which might cause a mistreatment by other NLP applications. The non-restrictive relative clauses including in the simplification process are the one which are introduced as an explanation of a certain noun phrase. This is easily recognizable by

¹ In this section, several examples are giving in English for a better understanding of the reader when possible. The examples given in English keep the same syntactic phenomena as the original Spanish sentences though. When given in Spanish, the English translation is provided if necessary.

either a human or a machine because it is introduced between commas within the sentence. The relative clause begins with a connector such as *que* or *quien*, which are the other indicators to let us classify the construction as relative subordinate. What can cause some trouble to an automatic SS system is the correct identification of the noun phrase and the ending of the relative clause. We can see a simple and representative example of this type of construction on the Spanish language and its simplification in the following Example (5):

- (5) a. *Juan, que es aún muy joven, consiguió el premio.*
 [Juan, who is still very young, got the prize.]
- b. – *Juan es aún muy joven.*
 [Juan is still very young.]
- *Juan consiguió el premio.*
 [Juan got the prize.]

- Effect: In this type of structure contains the relation cause-effect. The *cause* appears at the first part of the sentence and the *effect* appears afterwards. They are connected by a conjunction which indicates the end of the cause and the beginning of the effect. Therefore the splitting of the sentence will happen exactly at the conjunction's position and another effect connector such as *therefore* in English is introduced at the beginning of the second sentence as we can appreciate in Example (6). In Spanish the connector introduced will be “*Por lo tanto,*” at every *effect* case.

- (6) a. *The cat ate poisoned food, so it died.*
- b. – *The cat ate poisoned food.*
 – *Therefore, the cat died.*

- Cause: The same kind of relation cause-effect appears in this structure. However, the relation appears in the opposite order. The *cause* appears in this case at the second part of the sentence whereas the *effect* appears at first place. They will be connected by a

different kind of subordination causative connector such as *because* on the English language - Example (7) - and *porque* on the Spanish language. The output sentences will include the *effect* in the first position and the *cause* or *reason* in the second sentence.

- (7) a. *Dogs can't fly because they don't have wings.*
b. – *Dogs can't fly.*
– *Reason: They don't have wings.*

• Indirect speech to direct speech: This structure is currently simplified just on very specific cases. More precisely, in the cases where a communication verb such as *decir*, *comunicar* or *explicar* are followed by the relative *que* and a sentence concerning the communication of the speaker. Most of the communication verbs included for this task were extracted from *Diccionario combinatorio del español contemporáneo* (Bosque, 2004). The transformation follows is to introduce “:” between the first sentence and the second sentence, as we can observe in the following Example (8):

- (8) a. *El jugador dijo que el presidente estuvo con el equipo antes del partido.*
[The player said that the president was with the team before the match.]
b. – *El jugador dijo:*
[The player said:]
– *El presidente estuvo con el equipo antes del partido.*
[The president was with the team before the match.]

3.2 Regeneration stage

This is the stage concerning the last part of the simplification process. It was firstly introduced by Siddharthan (2002) in the creation of an automatic TS system. Once the original sentence has been split into several ones, there are still some unresolved

issues such as the simplified sentences order and anaphoric references which need to be tackled in this last stage.

3.2.1 Anaphoric references and noun phrase repetition

Since preserving the meaning of the original sentence is one of the main premises in TS, some noun phrases which should appear on an anaphoric way in the simplified sentences will be repeated instead and the use of pronouns will be considerably reduced. We can appreciate in the Example (6) on page 38 how the noun phrase “the cat” is repeated in both sentences. Although the readability of the sentence could be damaged, this will lead to a better understanding of the simplified sentences with no ambiguity. To improve the readability, these anaphoric references, albeit repeated, will appear as shortened as possible.

This noun phrase repetition is especially important in the sentences with non-restrictive clauses, as the noun phrase where the relative clause is attached must be correctly identified and repeated in the simplified sentence. However, this noun phrase often counts with a long amount of words, so that a reduction of the noun phrase is in those cases necessary (without substituting it by a pronoun).

3.2.2 Sentence reordering

The split phase gives us a set of new sentences with no order as output. Giving them a right order is in some cases essential to fully understand the message of the original sentence. Although most of the sentences keep the order as found in the original sentences, there are some cases where a sentence reordering is needed. This reordering is not a difficult task for a native Spanish but an automatic system might find it extremely

difficult. Therefore an algorithm is also included in Chapter 5 regarding the sentence order of the output sentences.

What is usually natural for a native speaker is to leave the order as it appears on the original sentences. However, there are certain embedded syntactic structures which need to be dealt more carefully. This is usually the case of relative clauses, which are a complement of a noun phrase in the middle inside the main sentence. It is the decision of the native speaker then to give a right order to these sentences. It is not a random decision though, as it is also related to the relative position of the relative clause within the sentence.

4. Corpus

A parallel corpus of Spanish original and simplified sentences is been built for the research. This was done manually by following the simplification rules given in the previous Chapter. Subchapter 4.1 explains in detail the parallel corpus creation process and Subchapter 4.2 shows the validation of the corpus by native Spanish speakers. This validation also concerns the rules considered in Chapter 3, as they are the same applied during the building of the corpus.

This corpus is the result of a long process of selecting the adequate rules for the simplification (Camacho Collados, 2013). It was necessary to decide the set of simplification rules prior to the creation of the final corpus. Once these rules were decided, the corpus was modified according to this set of rules. Since the set of rules is still extendable, the corpus could suffer more modifications in the future. However, this extension will not cause too much problem because of the nature of the simplification rules. They are mainly based on keywords rather than patterns, which makes the automatic search of rules within the corpus quite accessible.

The parallel corpus is envisioned to be used as a tool to create an automatic SS system. It is especially prepared and aligned to use supervised *Machine Learning* techniques. As the corpus is expected to be extended in the future, *Machine Learning* will be encouraged and will possibly improve the SS system. The corpus has also been a useful tool to create the Gold Standard for the evaluation experiments (Chapter 6).

4.1 Creation of the parallel corpus

The corpus chosen as a reference was the AnCora Corpus (Taulé et al., 2008), which consists of Spanish newspaper texts annotated at syntactic and morphological

level. Newspaper texts are quite representative of the natural language and complex enough for the simplification task. Once the corpus was transferred from the original XML format to text format, the sentences from the AnCora Corpus were manually simplified as explained in Chapter 3 in separate text files. On this way a parallel corpus of original and simplified texts was built. As we can see in Fig. 1, the original sentences and the simplified ones are easily aligned, as each original sentence is separated from each other on a new line, which is respected on the simplified part (right part on Figure 4) no matter how many new sentences have been created.

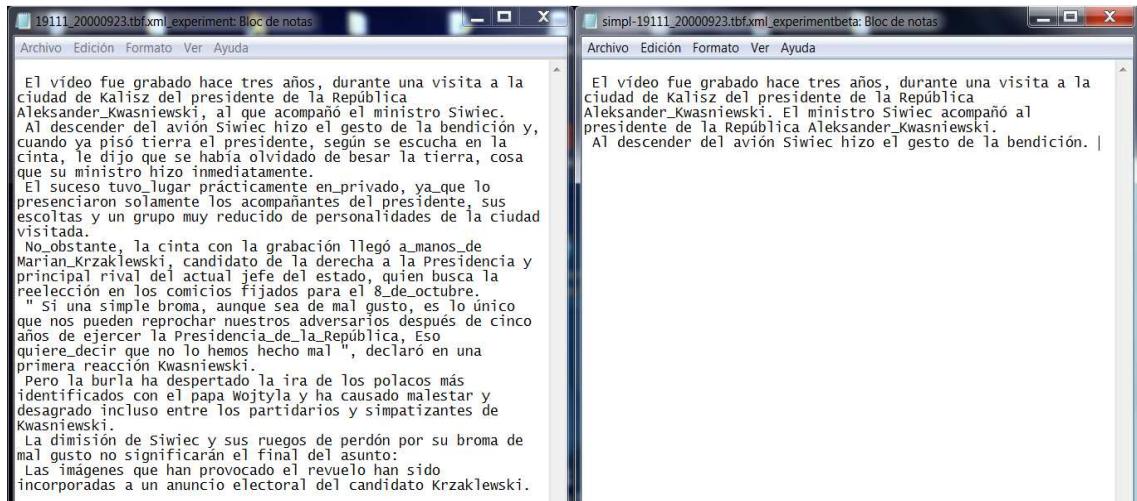

Figure 4: Creation of the parallel corpus in text format (Camacho Collados, 2013)

The corpus currently counts with 3000 original sentences and their respective simplified ones. It is already available for research purposes if required. Appendix A includes an example of an original text and its simplification from the parallel corpus.

4.2 Corpus validation

The validation of the corpus has been done regarding two issues (grammaticality and preservation of meaning), similar to the one used in Drndarević et al. (2013) for the evaluation of their SS system. To carry out this, some preliminary results were obtained from six native Spanish speakers (three of them linguists and three of them holding a non-related university degree). They required to fill three excel sheets (see Appendix B). The first one was to evaluate the grammaticality of the original sentences from AnCora corpus; the second one about the grammaticality of the simplified sentences from AnCora Corpus; and the third one concerning the preservation of meaning of original and simplified sentences. To do so, thirty complex sentences were randomly selected from thirty different texts of the corpus.

All the evaluations were done on a 1-5 scale. For the grammaticality measure, 1 means that sentence is completely a grammatical and the 5 that the sentence is completely grammatical. For the preservation of meaning, 1 means that there is no preservation of meaning at all and 5 that the meaning of the simplified sentence and the original is identical. Table 2 shows the total average for each evaluation and from the results we can appreciate how grammaticality is not damaged on the simplified sentences (4.74 without simplification – 4.66 with simplification). A paired two-sample t-test at the 0.05 level suggests that the difference is not statistically significant ($t(179)=1.513$; $p\text{-value}=0.132$)². There are even a few cases where the simplification actually improves the grammaticality of the original sentences.

² The results from the corpus validation have been analyzed by using the statistical program IBM SPSS Statistics 20. All the statistical tests and graphics throughout this research have been produced by this statistical program.

Table 2: Corpus validation (grammaticality and preservation of meaning)

	Grammaticality Original Sentences	Grammaticality Simplified Sentences	Preservation of meaning
Average	4.74	4.66	4.8
Positive (4-5)	95.6%	97.2%	98.9%
Neutral (3)	3.3%	2.8%	1.1%
Negative (1-2)	1.1%	0%	0%

Considering 4-5 as a positive attitude of the annotator towards the grammaticality /preservation of meaning, 3 a neutral attitude, and 1-2 a negative attitude, table 2 also shows the general results of the annotator's attitude. The grammaticality and preservation of meaning from simplified sentences get an incredibly positive attitude by the annotator (over 97% in both cases).

Regarding the inter-rater reliability for the preservation of meaning task, a statistical test at a 0.05 level was carried out among the six annotators. The results ($F(5,174)=1.577$, $p\text{-value}= 0.169$) show an inter-annotator agreement quite high.

5. Automatic Syntactic Simplification system

Once the corpus and the rules were clearly defined, a small automatic SS system was developed on the programming language *Python*. Only sentences containing two conjugated verbs are covered so far by the system. Further improvements need to be added to the system in order to be able to tackle sentences with more than two conjugated verbs.

The SS system is built following a three-stage architecture (analysis, transformation and regeneration) following the system developed by Siddharthan (2002). Each stage will be explained and evaluated separately. In general, the system is built in a way that it does not rely neither on any full parsers nor dependency structures, which has been the main origin of errors in previous TS attempts (Siddharthan, 2011; Drndarević et al., 2013). This is also coherent with one of the goals of the system to improve the performance of parsers. It is just based on word searches of the articulation points (Chandrasekar et al., 1996) and in a few particular cases, as we are going to see in following chapters, on shallow PoS taggers and verb lemmatizers. In the regeneration stage, system relies on noun chunking in most cases. Therefore the performance of this automatic system may be generally improved regardless of the performance of automatic taggers.

Another advantage of this approach is the adaptability to other close languages such as French, Italian or Portuguese. The way the system is developed without relying on specific language-related peculiarities allows an implementation for those languages relatively easy. All the syntactic phenomena treated in this research and the subsequent transformations are shared by all these Romance languages.

This Chapter includes the explanations of how the system was built. Subchapter 5.1 focuses on the analysis stage, Subchapter 5.2 shows the rules considered for the transformation stage and Subchapter 5.3 deals with the last phase, the regeneration stage.

5.1 Analysis stage

This stage takes the original sentence as input and decides whether simplifying it or not. It mainly relies on Part of Speech (PoS) tagging, word searches and, in a specific case, lemmatization. PoS taggers are only necessary in order to find the number of verbs in the sentence. As explained before, this research will include the simplification with no more than two conjugated verbs. To be more precise, this research intends to simplify sentences with two conjugated verbs, since sentences with only one conjugated verb will be considered as simples already.

Once this is done, the analysis stage will rely on raw word searches which was proved to be reliable indicators of whether simplifying or not in Medero and Ostendorf (2011). More specifically, conjunctions will usually be the indicator of simplifiable and also non-simplifiable sentences. The conjunctions allow us to detect the structures described in chapter 3 which are to be simplified. On a specific rule (indirect to direct speech), lemma searches would be also necessary in order to find the simplification pattern. In this stage we are not worried yet of where the splitting should be done and how it should be done. All these concerns will be studied in more detail in the following stage (transformation), which appears in the next subchapter.

This stage was based on a decision-tree model taking into consideration conjunctions indicator of possible simplification but also indicators suggesting not to simplify (*cuando, donde...*). This was possible because of the first assumption of only two conjugated verbs per sentence. That is the reason why indicators of no simplification become essential at this stage, especially for the coordinate sentences. Coordinate sentences make use of ambiguous conjunctions such us commas or “y” (and), which are used in many different kind of structures. Therefore identifying correct coordinate sentences is a relatively difficult task (Goldberg, 1999). The decision was to include these coordinators conjunctions at the very bottom of this decision-tree model even after the *no simplification* indicators. This decision may damage the recall of the analysis stage as

certain true coordinate sentences will not be recognized. However, it will surely improve the precision, which is actually most important than the recall for the simplification task.

Concerning the indirect to direct speech rule, a search of a bag of communications verbs is needed so that lemma search is essential. In this case, we use the AnCora XML documents provided by the corpus. These lemmas were semi automatically captured and exported to XML as explained in Taulé et al. (2008).

In the next Chapter, an experiment is carried out in order to find how the stage works in terms of precision and recall.

5.2 Transformation stage

Once the analysis stage has decided to simplify the input sentence, the transformation stage comes into place. At this stage, the system basically chooses a position to split the sentence and introduces new connectors if necessary. This differs a bit from the transformation stage of Siddharthan's text simplification architecture (Siddharthan, 2002), where the analysis stage were the one selecting the boundaries between clauses and the main sentence. This stage does not take into account the relation within the sentences nor the anaphoric references to be considered in the output sentences. This will be considered later on the regeneration stage.

In the particular example of the non-restrictive relative subordinates, the splitting is produced just after the relative *que*, *quien* or *quienes* where the comma is placed. These relatives must be preceded by a noun or a noun followed by an adjective. In the cases where this relative clause is not the end of the sentence, the simplified sentence split will usually end in the following comma of the sentence as we can appreciate in the Example (9). However, there are a few considerations to be taken about this rule. The first is that the main sentence should continue with a conjugated verb and even so, if the comma is followed by nouns, adjectives or prepositions (no more than four in total) and a comma,

the second comma will be taken as split indicator. To do so, PoS tags from the XML document are used.

- (9) a. *Los jugadores excluidos, que no se comportaron como profesionales, no jugarán más esta temporada.*
[The excluded players, who didn't behave as professional players, will not play anymore this season]
- b. – *** *no se comportaron como profesionales.*
[*** didn't behave as professional players.]
- *** *no jugarán más esta temporada.*
[*** will not play anymore this season]

On the other cases (cause, effect and indirect to direct speech), the sentences are split just once, i.e., the first output sentence appears in the first part of the original sentence and the second one appears in the second and last part of the original sentence. There are not embedded structures like in the sentences including relative clauses structures.

5.3 *Regeneration stage*

This is the last phase of the SS process. It is also the technically most difficult stage to handle automatically. After the splitting of the sentence on the transformation stage, many assumptions need to be taken in order to make these new simplified sentences readable and understandable. These assumptions are tackled in Chapter 4 but in this Subchapter we will treat them from the automatic point of view.

As in Subchapter 4.2, we are going to divide this task in two subtasks: anaphoric references and noun phrase repetition in Subsection 5.3.1 and sentence reordering in Subsection 5.3.2.

5.3.1 Anaphoric references and noun phrase repetition

This is the most challenging task in the whole SS process. As the original sentence is split, there are some links within the original sentence which may be lost while the simplification. Anaphoric references may appear at the end of the original sentence but may refer to a certain element of the beginning of the sentence and, after SS, this appears at a different sentence. There might be other problems at the discourse level as well. For instance, some anaphoric references at the original sentences referring to some element at a previous sentence may cause trouble to the simplification. However, at this stage this research is going to focus on the problems inside the sentence and not at the discourse level.

The structure with more problems at a practical point of view is again the relative subordinate. It is the one this research has focused on at this stage, as the noun phrase repetition is essential for the well understanding of the output sentences. The main decision is was to consider the closer noun phrase to the conjunction *que* or *quien*, unless there are other indicators which may lead to take a better decision. To consider noun phrase, no shallow parsers are used, as this caused more trouble from the beginning than deciding the noun phrase by other specific approaches. A noun phrase was considered to be combinations of adjectives, nouns and maximum a preposition such as *de* with a maximum length of eight words. This simple assumption seems to be enough in the vast majority of the cases of the parallel corpus. For the repetition of the noun phrase in the output sentence corresponding to the relative clause, it is exactly copied in most cases. In some other cases (where some proper nouns on capital letters are placed at the beginning), these nouns appear alone without its noun complements on the output sentences. In the Example (10), which we have previously studied for the transformation stage, the noun phrase *los jugadores excluidos* [the excluded players] is repeated without any change in both output sentences.

- (10) a. *Los jugadores excluidos*, que no se comportaron como profesionales,
no jugarán más esta temporada.
 [The excluded players, who didn't behave as professional players, will not play
 anymore this season]
- b. – *Los jugadores excluidos* no se comportaron como profesionales.
 [The excluded players didn't behave as professional players.]
- *Los jugadores excluidos* *no jugarán más esta temporada.*
 [The excluded players will not play anymore this season.]

5.3.2 Sentence reordering

Transformation stage gives a set of sentences with no order. The regeneration stage attempts to give a correct order to the output sentences. For the coordinated sentences, as well as the cause-effect subordinates and indirect to direct speech, this does not cause any problem in this matter. The logical decision of giving the order of the output sentences as they appear on the original sentences work perfectly.

For some non-restrictive relative subordinates containing embedded structures, the reordering of the output sentences is not a trivial issue. This issue becomes sharper as the number of conjugated verbs increase, so it is essential to start treating it at this simple stage of sentences with no more than 2 conjugated verbs. The decision to solve this issue was purely mathematical and it is based on the relative clause position. As we can see in Figure 5, the formula takes into account where the relative clause starts (including the noun phrase which complements), where it finishes and the length of the sentence.

If (position beginning relative clause + position ending relative clause < length (sentence)) →

Relative clause comes in the first place.

Las vacaciones de Luis, que no se presentó a trabajar ayer, le van a costar la destitución.

Rel. clause beg.: 3

Rel. clause ending: 11

Length sentence: 17

$3+11=14<17 \rightarrow$ a. *Luis no se presentó a trabajar ayer.*

b. *Las vacaciones de Luis le van a costar la destitución.*

Figure 5: Sentence reordering, relative clause example

We can appreciate in the example of Figure 5 how the relative clause ends up being at the first place while the rest of the sentence comes afterwards. If the condition were not fulfilled, the position would be inverted. This basic approach to handle the problem of sentence reordering on embedded structures gives a good understanding of the resulting output sentences.

6. Evaluation

This Chapter presents the evaluation in three different ways, each of them corresponding to a different goal. Subchapters 6.1 and 6.2 tackle two extrinsic evaluations whereas Subchapter 6.3 evaluates the automatic simplification system. Subchapter 6.1 treats the first main goal of this research: SS for MT. As explained in previous Chapters, simplification is carried out on the source language (Spanish) and the target language will be Korean and Chinese in this case. The second evaluation will be about improving the understandability of text for foreigners learning Spanish. To end the evaluation, Subchapter 6.3 will attempt to give a first evaluation of the automatic simplification system for sentences with two conjugated verbs. It is also important to notice that all the evaluations include in some way the parallel corpus.

6.1 Syntactic Simplification for Machine Translation

In this Subchapter, the effect of SS in MT will be evaluated by a comparison between direct MT systems and MT systems which previously have used SS on the source languages. There will be two different evaluations concerning different target languages, the first one taking Korean as the target language and the second one taking Chinese as the target language. Spanish will be in both cases the source languages.

The experiments settings are similar for both experiments. Thirty complex sentences have been randomly selected from thirty different texts of the parallel corpus created along this research (see Chapter 4), including their respective simplified ones. The thirty original sentences were translated respectively by a Spanish-Korean and a Spanish-Chinese translator, which was considered as Gold Standard.

The Spanish-Korean and Spanish-Chinese Google Translate was the MT system for the evaluation. First, the original sentences were introduced directly on the automatic

translator and the output sentences were stored, what we will call simply MT. Second, SS was used prior to the translation (see Subchapter 1.2 to understand the implementation of SS in the MT process). This second output will be called SS+MT. The simplified part of the thirty original sentences (taken from the parallel corpus) was introduced on Google Translate to produce three new outputs.

An evaluation of both ways was then carried out among native Korean and Chinese. The native speakers were asked to evaluate the grammaticality of the output sentence and compare each output with the Gold Standard regarding its preservation of meaning. The grammaticality was evaluated by following a 1-5 scale where 1 indicates a totally non grammatical sentence and 5 indicates a fully grammatical sentence. The preservation of meaning was also done by following the 1-5 scale in a similar way. 1 means that the output sentence does not preserve at all the meaning of the Gold Standard sentence and 5 indicates a total preservation of meaning. Appendix C shows a summary of the Excel files which the native Korean evaluators were asked to fill in, whereas Appendix D includes the native Chinese evaluators' files.

Subchapter 6.1.1 gives a small description of the peculiarities of the Korean language and shows the results from the experiment explained above. Subchapter 6.2.2 focuses on these concerns but considering Chinese as the target language in this case.

6.1.1 Spanish-Korean

Korean language, so-called *Hangeul*, uses a phonemic writing system which is composed of 14 consonants and 10 vowels. Unlike general phonemic writing systems such as Spanish, it combines consonants and vowels into syllabic units. The total number of linguistic units which can be made as a result of the combinations of consonants and vowels reaches 11,172. For example, 문자 is composed by three consonants ㅁ, ㄴ, ㅈ and two vowels ㅏ, ㅓ.

Korean was considered to be a Ural-Altaic language until the end of 20th century. It shares some characteristics with the Ural-Altaic languages: the Subject-Object-Verb structure, the morphologically richness and the agglutination among others. However, because of the lack of cognates with this language family and the highly amount of loanwords from the Chinese language, Korean language is currently defined as an isolated language (The National Institute of the Korean Language, 2008). Spanish and Korean are therefore considered to be far language with very few characteristics in common.

The MT experiment setting is prepared as explained at the beginning of Subchapter 6.1. There are some preliminary results obtained from three native Korean evaluators holding at least a university postgraduate degree. They were asked to fill two Excel files (see Appendix C) concerning the grammaticality and preservation of meaning from the output sentences given by the MT directly (MT) and output obtained by applying SS prior to MT (SS+MT).

Spanish-Korean MT systems have not been as developed as other pair of languages. According to the native Korean evaluators of this research, the output sentences given by the Spanish-Korean Google Translate MT system are poorly constructed and in many cases not understandable. This is reflected on the results which are summarized on Table 3.

Table 3: Spanish-Korean MT results, grammaticality.

	Grammaticality MT	Grammaticality SS+MT
Average	2.6	3.07**
Positive (4-5) ³	15.6%	31.1%
Neutral (3) ⁴	40%	44.4%
Negative (1-2) ⁵	44.4%	24.4%

**: difference statistically significant at the level 0,001

³ Positive attitude by the evaluator towards the sentence grammaticality (scores 4 and 5).

⁴ Neutral attitude by the evaluator towards the sentence grammaticality (score 3).

⁵ Negative attitude by the evaluator towards the sentence grammaticality (scores 1 and 2).

According to a paired t-test, the difference between the grammaticality score averages of MT and SS+MT output sentences is statistically significant ($t(89)=-5.205$, $p\text{-value}<0.001$). This is a considerable difference taking into account that the Gold Standard sentences have been translated directly from the original sentences and not the simplified ones. One of the reasons may be the usual sentence length of both languages. Whereas Spanish sentences accept long and complex sentences like the ones included on the test set, Korean language appreciates short and simpler sentences. This is one of the reasons why Spanish-Korean MT system backfires on these complex sentences. SS has therefore solved several problems posed by the MT system and the grammaticality average score has increased from 2.6 to 3.07 on a 1-5 scale, which is a significant improvement. We can see on Figure 6 how the average is clearly improved on every evaluator (S1, S2 and S3).

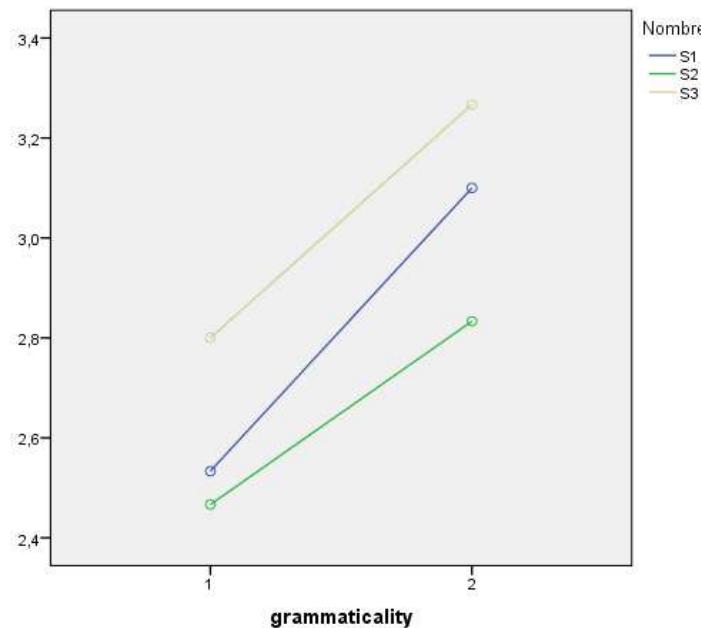

Figure 6: Spanish-Korean MT evaluators' graphic, grammaticality

Even though each evaluator has his own subjectivity about the grammaticality task, this is not relevant to compare direct MT and SS+MT. An ANOVA test carried out among the results of the experiment shows that the evaluators' attitude toward this

comparison is extremely similar ($F(2,87)=0.409$, $p\text{-value}=0.666$), i.e., the grammaticality improvement is clear regardless the evaluator.

The results from the preservation of meaning task are summarized on Table 4. The first column (MT) shows the results from the preservation of meaning between direct MT output sentences and the Gold Standard. The second column (SS+MT) shows the results from the preservation of meaning between SS+MT and the Gold Standard. In this case, the meaning is better preserved by SS+MT. The difference is also statistically significant according to a t-test ($t(89)=-6.183$, $p\text{-value}<0.001$). As we can see from the Table 4, the poor meaning preservation obtained by MT (more than 50 % of the sentences got a negative attitude from the evaluator) are highly improved by using SS prior to MT (the sentences with a negative attitude from the evaluator is in this case quite below 50%).

Table 4: Spanish-Korean MT results, preservation of meaning

Preservation of meaning between Gold Standard and... ->	MT	SS+MT
Average	2.44	3.02**
Positive (4-5)	18.9%	28.9%
Neutral (3)	24.4%	35.6%
Negative (1-2)	56.7%	35.6%

**: difference statistically significant at the level 0,001

This significant difference between both tasks is also due to one of the main drawbacks of MT: handling long and complex sentences. The splitting rules considered in this research attempts to solve this MT problem, especially in MT systems poorly developed like the Spanish-Korean treated in this chapter.

As we have observed before in the grammaticality task, the results from each evaluator show a clear improvement on the meaning preservation task by applying SS, as we can appreciate from Figure 7. An ANOVA test shows how this improvement is similar among the three annotators regardless their particular results on either MT or SS+MT ($F(2,87)=1.919$, $p\text{-value}=0.153$).

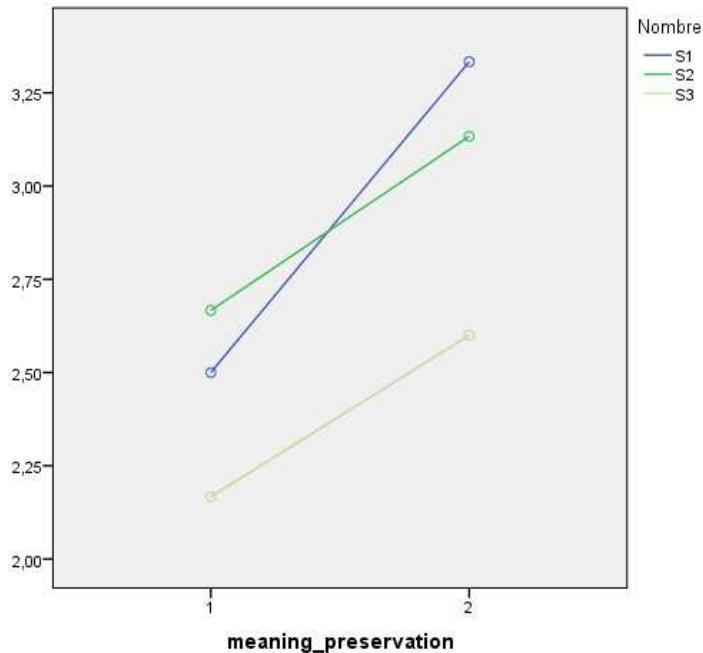

Figure 7: Spanish-Korean MT evaluators' graphic, preservation of meaning

6.1.2 Spanish-Chinese

Chinese language, so-called *Han-yu*, belongs to the Sino-Tibetan languages family. Around one-fifth of the world population uses Chinese as their native language. It is ideographic but the characters have suffered a process of encoding with the time. Some of the main characteristics of the Chinese language in contrast to the Spanish language are the following ones: monosyllabic, tonal, use of measure words and Subject-Predicate-Object word order (Gong, 2001). Each Chinese character represents a monosyllabic Chinese word or morpheme (男 (man), for instance). These characters have full meaning when found alone and the combinations with other characters enable the creation of new words (男 (man) + 孩子 (kid) → 男孩子 (boy)). Therefore, as with the Korean language, Spanish and Chinese are very distant languages in terms of syntaxis and morphology.

As far as the Spanish-Chinese MT experiment is concerned, the general setting is the same as the one prepared for the Korean language explained in Subchapter 6.1 (see Appendix D). Some preliminary results were obtained from three graduated native Chinese speakers. They were asked to perform two tasks: First, evaluating the grammaticality and preservation of meaning of the output sentences given by the Google Translate Spanish-Chinese MT system taking original sentences as the input (MT) and second, evaluating the same for the output sentences given by the Google Translate Spanish-Chinese MT system considering the syntactically simplified sentences as the input (SS+MT). The results obtained from the evaluation about the grammaticality task are summarized on Table 5.

Table 5: Spanish-Chinese MT results, grammaticality

	Grammaticality MT	Grammaticality SS+MT
Average	2.41	2.62*
Positive (4-5)	12.2%	12.2%
Neutral (3)	31.1%	44.4%
Negative (1-2)	56.7%	43.3%

*: difference statistically significant at the level 0.05

As we can observe from Table 5, the grammaticality is improved when applying SS prior to MT. The difference is statistically significant at the 0.05 level according to a paired t-test ($t(89)=-2.074$, $p\text{-value}=0.041$). This difference is slightly smaller than the one obtained in the Korean experiment. More evaluators will be needed in the future (or finding an accurate automatic evaluation metric for the task) in order to obtain the real improvement on this task. As we can see on Figure 8, the task was handled in a different way by the three evaluators and the comparison between the grammaticality of MT and SS+MT may not be totally accurate. An ANOVA test let us confirm this graphical impression: $F(2,87)=11.727$, $p\text{-value} < 0.001$. This test suggests getting more evaluators to obtain more reliable results.

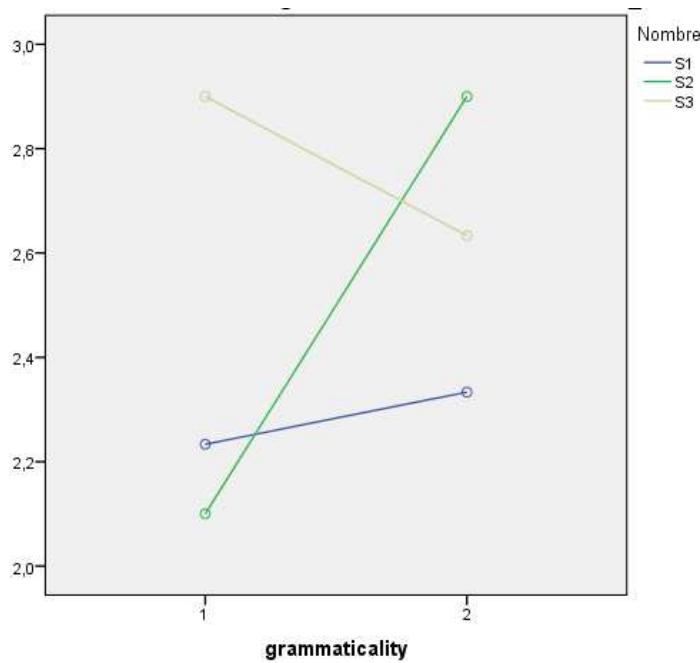

Figure 8: Spanish-Chinese MT evaluators' graphic, grammaticality

The meaning preservation results, which are the most important source to check the improvement of a MT system, were even more promising than the one regarding the grammaticality task. These results are summarized on Table 6. The meaning preservation average obtained by applying direct MT got the extremely low score 1.82, with 81.1% of the sentences obtaining a negative attitude from the evaluator. These results, even being still low for a MT system, show an important improvement by applying SS prior to the translation. The average reaches a 2.18 score and the percentage of sentences with a neutral or positive attitude by the evaluators is considerably raised, whereas the percentage of sentences with a negative attitude from the evaluator decreases until 65.6%. The average difference between MT and SS+MT for the meaning preservation task is even statistically more different than in the grammaticality task according to an paired t-test ($t(89)=-3,734$, $p\text{-value}<0.001$).

Table 6: Spanish-Chinese MT results, preservation of meaning

Preservation of meaning between Gold Standard and... ->	MT	SS+MT
Average	1.82	2.18**
Positive (4-5)	4.4%	8.9%
Neutral (3)	14.4%	25.6%
Negative (1-2)	81.1%	65.6%

**: difference statistically significant at the level 0.001

In this case, the results of each evaluator show an improvement (neutral correlation in one case) of the MT system by using SS (see Figure 9). However, the improvement is not regular according to an ANOVA test ($F(2,87)=11.600$, $p\text{-value} < 0.001$). Therefore the inter-annotator agreement on the Spanish-Chinese experiment is not quite high in general. Even though the improvement of the Spanish-Chinese MT is clear by using SS, more evaluators will be needed in the future to state the actual power of SS for this pair of languages.

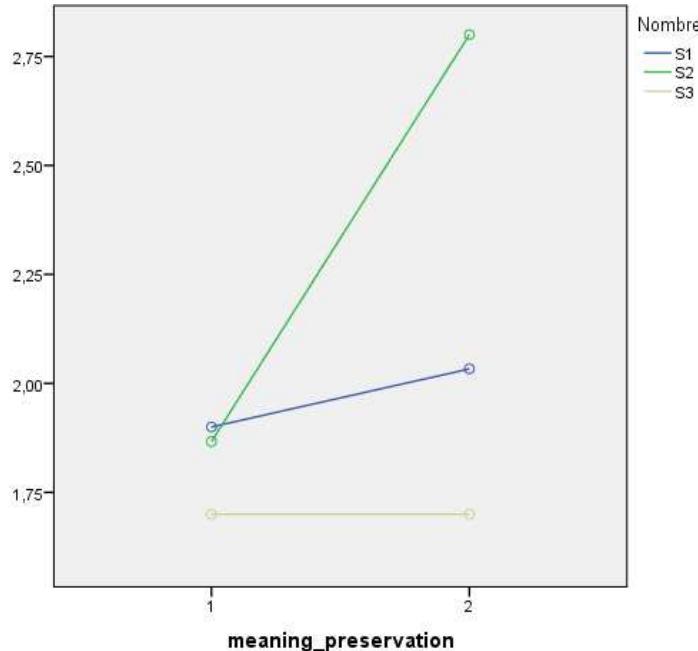

Figure 9: Spanish-Chinese MT evaluators' graphic, preservation of meaning

6.2 Foreigners learning Spanish

The research includes an extrinsic evaluation to check whether this approach may improve the understanding of a text by Spanish learners or not. Since the simplification rules intend to make sentences simpler, it would be interesting to know if it could also make texts more understandable for people with difficulty at reading. The main drawback of the approach is the readability, as there are some noun phrases which are repeated within sentences and it makes the reading sometimes slower. However, sentences become shorter and simpler after the simplification, which for certain parts of the population is a huge advantage in order to fully understand a text. For foreigners learning Spanish, there are certain structures which are difficult to understand as they usually differ from their native constructions.

Twenty four Spanish learners at the Faculty of *Traducción e Interpretación* in Granada University agreed to collaborate in this project. The participants had a native language other than Spanish. These languages were German, Bulgarian, Russian and French. They were divided in two groups of twelve participants each: A and B. Group A participants were given two original texts from AnCora Corpus and were asked to answer eight multiple-choice questions about them. It was a reading-comprehension test. Group B students were asked to do the same but from the group A's simplified texts. These simplified texts belong to the parallel corpus created along this research. Appendix E includes the tests given to both Group A and B students. The participants of each group had a similar level of English: five participants with an advanced level (C1-C2 according to the Common European Framework of Reference for Languages) of Spanish and seven with an Intermediate level (European Framework of Reference for Languages) Table 7 summarizes the characteristics about all the participants of the experiment.

Table 7: Summary of the participants in the reading-comprehension test

	A: Original text	B: Simplified text	Total
Participants	12	12	24
Intermediate	7	7	14
Advanced	5	5	10
Age average (years old)	24.2	22.6	23.4
Men	2	1	3
Women	10	11	21

The results obtained from the text were processed and summarized on Table 8. The results are given in percentages of correct answers. Surprisingly, the participants from group A (original texts) got a higher amount of right answers than the participants from group B (simplified texts). Group A obtained 82.3% of correct answers in contrast to the 79.2% obtained by group B. However, after applying an un-paired t-test at 0.05 level ($t(22)=-0.457$, $p\text{-value}=0.652$), we concluded that this difference is not statistically significant. Therefore these results suggest that the text comprehension has not been affected by SS. It does not improve the comprehension but it does not damage it either.

Table 8: Results from the reading-comprehension test

Correct answers	A: Original text	B: Simplified text
Total	82,3%	79,2%
Intermediate	82,1%	74,5%
Advanced	82,5%	87,5%

Regarding the Spanish level within the participants, it is interesting to notice how the simplification affects in a different way to advanced and intermediate students. It is quite unexpected the way the simplification damage the comprehension of intermediate level readers, whereas it slightly improves the performance of advanced readers. This may be due to the similar results obtained by intermediate and advanced readers in the group A. Group B (simplified text) obtained in their task more predictable results, as

intermediate level students got a 74.5% of correct answers in contrast to the 87.5% obtained by the advanced.

6.3 Automatic Syntactic Simplification system

For the automatic SS system evaluation, the AnCora Corpus XML documents provided were used. As explained in Taulé et al. (2008), the corpus was semi automatically tagged. These documents were fully parsed so PoS and lemmas were able to be extracted in the few cases when it was necessary. Since the automatic SS system currently just tackles sentences containing two conjugated verbs, a set of 40 sentences of two conjugated verbs were selected (see Appendix F). The selection process was done by following a random process. Every sentence was randomly selected from an AnCora Corpus text. There is no more than one sentence selected from a specific text. Therefore 40 different texts were necessary for the extraction of all the sentences to be used as a test set.

Since these 40 texts belong to the original part of the parallel corpus, the simplified part of the corpus was taken as a reference (Gold Standard) in order to evaluate the system. The clear alignment between sentences in the parallel corpus (as explained in Section 4), enabled an easy preparation of this test set and Gold Standard sentences. From the simplified sentences of the corpus, we found that 30 sentences were in some way simplified and 10 sentences were not simplified.

The evaluation was then divided in three parts. Firstly, the analysis stage is evaluated on Subsection 6.3.1 and it consists of checking whether the simplification should be carried out or not. Secondly, whether the sentences chooses the right case to simplify and it chooses the right position is evaluated, which is the transformation phase (Subsection 6.3.2). Thirdly, the results from the regeneration stage are shown on Subsection 6.3.2. This is done by following a 0-2 scale in contrast to the two other phases. To end with, Subsection 6.3.4 summarizes all these results considering the system

as a whole. It shows total averages taking an original sentence as input and giving the final simplified sentences as an output.

6.3.1 Analysis stage

As explained in the Subchapter 5.3, the analysis stage is the module in charge of deciding whether simplifying the input sentence or not. It mainly relies on finding the simplification articulation indicators and no simplification indicators. It also relies on PoS tagging to find out the number of verbs inside the sentences (which was not necessary in this case because of the test set selection process) and in a specific case, verb lemmatization as well.

The analysis stage takes an individual sentence from the test set as input and decides whether simplifying the sentences or not. The output of a single sentence takes only two values then: True for a sentence to be simplified and False for a sentence which does not need simplification. The results from the analysis stage are shown on Table 9.

Table 9: Analysis stage results

	Simplification	No Simplification
Gold Standard (n. of sentences)	30	10
Correct	28	10
Wrong	2	0
Precision:	100%	
Recall:	93.3%	

As we can appreciate from Table 9, there were 12 sentences which were not simplified by the system and 28 correctly simplified. From the 12 simplified sentences, two of them should have been simplified. This makes the recall not be perfect and gets a score of 93.3%, which is still extremely high. Since the main applications of this system

are mainly extrinsic, the mistakes of recognizing simplifiable sentences by the system are not quite important because they will not damage the performance of external applications such as MT (obviously in those cases they will not improve it either). In terms of precision, the analysis stage obtains a remarkable 100%. This means that there is no a single sentence simplified when it should not be simplified.

Therefore these results show that identifying simplifying patterns is not a difficult task and it can be done by basically using raw word searches. There were only three cases where verb lemmatizers were also needed (indirect to direct speech structures). However, this does not cause any problem to the automatic lemmatizers due to the rich variety of endings in verbs in the Spanish language making the automatic detection of the lemma quite an easy task. This means that the performance of the analysis stage does not rely on the performance of automatic parsers, which is quite encouraging to adapt this system to other Romance languages such as French, Italian and Portuguese.

As the automatic system is expected to be extended in order to handle sentences containing more than two conjugated verbs in the future, these results show that an induction from the 2-conjugated verb case is quite likely to succeed. Whether simplifying a sentence or not may be a not so difficult task regarding these results, which is a solid beginning for future improvements. The development of this complete automatic system may need further modifications in the transformation and regeneration stage though.

6.3.2 Transformation stage

The splitting of the original sentence is carried out on the transformation stage. The correct identification of the position where the splitting should be done and the simplification case are crucial at this point. This would lead to a clean transformation and a well understanding of the output sentence, as only a few corrections will be made later on the regeneration stage.

The same test set is used at this stage for the evaluation. We have therefore 28 sentences to be split at this stage. The system correctly selects the positions of the clauses and the simplification cases in the 100% of the sentences from the test set and makes just a single mistake in the transformation of the sentences. Therefore, the accuracy of the transformation stage reaches 96.43%. This result is already quite promising regardless the regeneration stage. It is also important to notice that the mistake produced by the system does not damage drastically the meaning of the original sentence –see Example (11). This is due to the correct identification of the case but the incorrect application of the transformation rule. In Example (11), we can appreciate how the subject ellipsis of the Spanish language on the subordinate clause has lead to the error. This is one of the main problems to handle automatically the Spanish language that should be studied deeply. However, the system usually handles well this subject ellipsis on the regeneration stage and in this particular case the general meaning of the output sentence is not seriously damaged.

- (11) a. Symplication system general resula. *Ivanov también afirmó que estaba "muy satisfecho" tras su "provechosa" conversación con Pérez Roque.*
 b. *Ivanov también afirmó: estaba "muy satisfecho" tras su "provechosa" conversación con Pérez Roque.*
 c. (Gold Standard) *Ivanov también afirmó estar "muy satisfecho" tras su "provechosa" conversación con Pérez Roque.*

It is important to highlight the impressive detection of the coordination by the system so far. Having a set of words and combination of words which are the indication of each case is proved to be a simple but reliable approach to handle coordination. Especially significant for this case is the bag of words which are indicators of no simplification, as the coordinators connectors are in most cases ambiguous (“,”, “y”) and do not often indicate any coordination.

6.3.3 Regeneration stage

Once the splitting phase is done, regeneration stage attempts to fix some missing or broken links between the output sentences. This stage is the one causing most practical problems to the simplification. Even though it seems that all the transformation are already done in the previous stage, there a lot of important issues on the output sentences which need to be fixed. It is not an easy task for an automatic system to decide whether to use anaphoric references or not and the position where they should be included. It is also quite hard to correctly identifying the boundaries of the relative clauses which are attached to noun phrases (the boundaries of the noun phrase are easily found either). These are the reason why this stage is the most challenging in the whole SS process.

We continue with the same test set used in previous stages for the evaluation. 27 sentences which are already split on the transformation phase and need to be fixed on some cases. Each of the original sentences taken as an input counts now with one and most cases two output sentences like in the Example (12), extracted from the parallel corpus:

- (12) a. *El rival por el oro va a ser Rusia, que se impuso a Portugal.*
 b. *–El rival por el oro va a ser Rusia.*
 – *** *se impuso a Portugal.*

There is an empty space in the second output sentence (***) which needs to be filled by an appropriate noun phrase. This will be done in the regeneration stage. In this particular example, there are two tasks to be done by the regeneration module of the system. The first one is correctly identified the noun phrase which is attached to the relative clause “que se impuso a Portugal” on the original sentence. In Subchapter 5.3 it is explained how the system deals with this in complicate cases where the noun phrase is

not easily identified. However, this case is quite simple as the noun Rusia is not approached by other nouns or adjectives which could make the task harder. Therefore, the system correctly selected Rusia as the noun phrase to be repeated on the second output sentence. Rusia will act as the subject of the new sentence then.

The second task which needs to be done on the regeneration stage is the reordering of the sentences. By applying the simple algorithm explained on Subchapter 5.3.2, the regeneration module correctly decided to keep the order as it appears in Example (12). Comparing the output results to the Gold Standard, this reordering task actually gets a 100% of accuracy on the test set. The 27 output sentences were given the correct order by the system. This means that the system tends to select the most natural order in all cases.

A general evaluation was done for the regeneration stage. Each output from the 27 already split sentences was given a 0-2 score. 2 means that the output is exactly same as the Gold Standard. 1 means that the output has the same meaning as the Gold Standard but something has been modified on a different way, just affecting the readability. 0 means that the meaning of the original sentence is on some way changed by the regeneration. The general results obtained by the regeneration module (including all the subtasks) are shown on Table 10.

Table 10: Regeneration stage results

	Score	0	1	2
Number of sentences		1	8	18
Percentage		3.7%	29.6%	66.7%
Average:	1.63			

As we can appreciate on Table 10, 18 out of the 27 sentences (66.7%) were correctly regenerated according to the Gold Standard, which is a remarkably high percentage taking into account the complexity of this module. The score average of the system is 1.63. This result is quite promising, as a few improvements may lead to an

almost perfect score (2) by the system. Only one sentence got a 0 score, which is shown in the Example (13) where we can observe how the identification of a noun phrase attached to a relative clause was incorrectly handled.

- (13) a. *Varios centenares de personas acudieron al palacio Brongniart, sede simbólica de la Bolsa parisiense. *** amaneció cubierto con los colores de Euronext, el amarillo y el azul, en forma de bandas situadas entre las catorce columnas de la fachada del edificio.*
- b. *Varios centenares de personas acudieron al palacio Brongniart, sede simbólica de la Bolsa parisiense. La Bolsa parisiense amaneció cubierto con los colores de Euronext, el amarillo y el azul, en forma de bandas situadas entre las catorce columnas de la fachada del edificio.*
- c. (Gold Standard) *Varios centenares de personas acudieron al palacio Brongniart, sede simbólica de la Bolsa parisiense. El palacio Brongniart amaneció cubierto con los colores de Euronext, el amarillo y el azul, en forma de bandas situadas entre las catorce columnas de la fachada del edificio.*

The noun phrase selected by the system to be repeated on the second sentence was La Bolsa parisiense while the correct one was El palacio Brongniart. The system failed to identify the link between the relative clause and the main sentence. What failed was the recognition of the apposition sede simbólica de la Bolsa parisiense from the noun El palacio Brongniart. However, the system, as the score states, found correctly or almost correctly the rest of the noun phrases of the test set.

In Example (14) below, we can appreciate how the second output sentence lacks a subject, which is totally right for the Spanish language. The module should improve in this matter though, as the subject will give a much better understandability of the sentence.

- (14) a. *Patrick Kluivert, autor del primer tanto del equipo azulgrana, aumentó a 13 su cuenta en el presente campeonato. *** ya es líder en solitario de la clasificación de goleadores del Barcelona en la Liga 1999-2000, con uno de ventaja sobre Rivaldo.*
- b. *Patrick Kluivert, autor del primer tanto del equipo azulgrana, aumentó a 13 su cuenta en el presente campeonato. Ya es líder en solitario de la clasificación de goleadores del Barcelona en la Liga 1999-2000, con uno de ventaja sobre Rivaldo.*
- c. (Gold Standard) *Patrick Kluivert, autor del primer tanto del equipo azulgrana, aumentó a 13 su cuenta en el presente campeonato. Patrick Kluivert ya es líder en solitario de la clasificación de goleadores del Barcelona en la Liga 1999-2000, con uno de ventaja sobre Rivaldo.*

Example (15) identifies correctly the noun phrase and repeated in the output sentence. Obviously the preservation of meaning between the Gold Standard and the output sentence is total. However, in this case, where a proper noun is included, it is suggested reducing the length of the noun phrase in order to improve the fluency of the sentence. These minor changes are not only stylistic, but also help sentences to be better processed by other NLP applications.

- (15) a. *El pasado lunes, el Tribunal Correccional condenó a diez años de cárcel, pena máxima por asociación de malhechores con fines terroristas, a "Pototo" y a su antiguo lugarteniente, el francés Daniel Derguy. *** hoy cumple 59 días en huelga de hambre.*
- b. *El pasado lunes, el Tribunal Correccional condenó a diez años de cárcel, pena máxima por asociación de malhechores con fines terroristas, a "Pototo" y a su antiguo lugarteniente, el francés Daniel Derguy. El francés Daniel Derguy hoy cumple 59 días en huelga de hambre.*

c. (Gold Standard) *El pasado lunes, el Tribunal Correccional condenó a diez años de cárcel, pena máxima por asociación de malhechores con fines terroristas, a "Pototo" y a su antiguo lugarteniente, el francés Daniel Derguy. Daniel Derguy hoy cumple 59 días en huelga de hambre.*

As we have seen in the previous Examples (14) and (15) with score 1, the meaning of Gold Standard and output sentences is preserved, as in the remaining sentences with score 1. Therefore we can consider sentences with a score of 1 or 2 to be positively simplified. As we could observe from Table 10, there is a huge percentage of the test set with a score of 1 or 2. There are exactly 26 sentences out of 27 (96.3%) which are positively handled by the system at this stage, which is a high rate.

6.3.4 General results

Considering the original sentences as the input and the simplified sentences after the regeneration stage as the output, we obtain the following results shown in Table 11. Perfectly simplified are the sentence obtaining perfect scores at each stage of the system whereas positively simplified include the sentences which are correctly handled by the analysis and transformation stage and obtain a 1-2 score at the regeneration stage. Positively simplified sentences are the ones which have been simplified without damaging the meaning of the original sentence. The incorrectly simplified sentences include the sentences which have not been well simplified in either analysis or transformation stage or have obtained a 0 score at the regeneration stage. To summarize, incorrectly simplified sentences are the one which either does not preserve the meaning of the Gold Standard or have not been simplified when they were supposed to.

Table 11: Symplification system general results

	Total	Percentage
Input sentences	40	100%
Sentences simplified by the system	28	70%
Positively simplified	26	92.9%
Incorrectly simplified	2	7.1%
<i>Perfectly simplified</i>	18	64.3%
Sentences not simplified by the system	12	30%

The general results obtained are quite promising, as 92.9% of the simplified sentences were positively handled by the system. These are the sentences which suffered the splitting process of the simplification process and preserve the meaning with the original sentence (comparing it to the Gold Standard). There were just two sentences out of forty which were actually bad simplifications by the system. One was incorrectly handled on the transformation stage and the other one incorrectly regenerate at the last stage. This last stage is the most complex stage within the simplification process and the one which needs to get more adjustments in the future. However, there were a 64.3% of output sentences corresponding word by word to the respective Gold Standard at the end of the simplification process. This is an incredibly huge percentage considering the complexity of this task and the early stage of this project.

These results and the way the system has been developed suggest that an automatic syntactic simplification system is possible if a careful selection of the rules is done. One the main advantage of this approach is its adaptability, so further researches should focus on adapting it to be able to handle longer and more complex sentences.

7. Conclusions and future work

A new SS system based on splitting complex sentences is proposed. The general architecture of the system was inspired by the TS architecture proposed in Siddharthan (2002). The system is envisioned to be used as a preprocessing tool for other NLP applications such as Text Summarization, Information Extraction, Parsing and Machine Translation. The latter is the NLP application evaluated on this research, taking Spanish as source language and Korean and Chinese as target language of the MT system. The performance of the MT system evaluated has been improved by using the SS proposed prior to the translation. This approach has partially solved one of the main drawbacks of MT in handling long and complex sentence. A first version of the automatic SS system has also been analyzed and evaluated intrinsically. This SS system is expected to be extended in order to properly handle longer and more complex sentences.

This Chapter presents the main results obtained from the research together with a general overview of the project on Subchapter 7.1. Subchapter 7.2 addresses some directions for future research concerning the improvement of the system and a deeper analysis of evaluation metrics.

7.1 Main observations

The approach of this research differs from previous TS approaches in how the system is built and its applications. The SS system proposed relies on noun chunking rather than dependency structures, unlike previous works (Klebanov et al., 2004; Siddharthan, 2011; Drndarević et al., 2013). Its adaptability is one of the main advantages. The system is adaptable to close Romance languages such as Catalan, French, Italian or

Portuguese by just making a few adjustments of the rules to the specific language. Although it currently handles only complex sentences of two conjugated verbs, it is easily extensible to process longer sentences by applying an induction process. New rules can be also added to the system without damaging the remaining ones.

The results from the evaluation state that a reliable syntactic simplification system is feasible by considering these splitting rules. A few adjustments need to be made especially on the regeneration stage, focusing on the subject ellipsis problem on the Spanish language and the improvement of the specific noun chunkers.

A parallel corpus of Spanish original and simplified sentences has been built on this research. It is envisioned to be used as a tool in order to create an automatic Syntactic Simplification system. It has been later validated by native Spanish speakers with the expected results. Neither the grammaticality nor the preservation of meaning on newswire texts are damaged by the syntactic modifications. This validation was essential prior to carry out other extrinsic evaluations.

As far as Machine Translation is concerned, Syntactic Simplification has been proved to be a quite reliable and easy to implement monolingual resource for underdeveloped systems. Spanish-Chinese and Spanish-Korean Statistical Machine Translation systems have been evaluated on this research. The preliminary results state that the application of the Syntactic Simplification proposed prior to the translation is really beneficial on both cases. However, more evaluators will be needed in order to state the real improvement, especially on the Spanish-Chinese case according to the inter-annotator agreement results. Other languages should be taken into consideration as target languages in the future. In the next Subchapter, some directions for future research on this matter are indicated.

7.2 Future work

As pointed out in the previous Subchapter, further research should focus on the development of the Syntactic Simplification system and extend it to handle every kind of sentence from the natural language. Different rules may be also added in the system and evaluate its impact on extrinsic applications other than Machine Translation (Text Summarization, Information Extraction and parsing, for instance). Modules at the lexical and semantic level could be implemented in the system in order to solve some ambiguity problems on these extrinsic applications.

One of the main drawbacks of this approach is the lack of solutions at the discourse level. This system does not include any anaphora and co-reference resolution modules, which could give more accurate simplifications in some cases. Further research should focus on how to implement these modules to the system.

A possible way to improve the system will be to extend the parallel corpus which would enable to apply Machine Learning techniques like in Specia (2010). The future system could be hybrid by using the syntactic rules and Machine Learning in some complicated cases.

As far as the evaluation is concerned, further researches on evaluation metrics would be desirable. Text Simplification is a field which has always lacked of a widely accepted evaluation metric. This is mainly due to the different external applications for what the Text Simplification system is built. In this case, extrinsic evaluation metrics would be more indicative of how the system works rather than evaluating the system itself. A reliable baseline for extrinsic applications such as Machine Translation would be necessary prior to future improvements of the system. However, Machine Translation metrics such as BLEU are not excessively reliable because of the splitting nature of the simplifications. Therefore other automatic or human Machine Translation evaluation metrics should be considered and investigated.

APPENDIX

Appendix A: Original and simplified text in the parallel corpus (Example)

Original text:

La española Margarita_Fullana logró hoy, sábado, la medalla de bronce en la prueba de "mountain-bike" o bicicleta todo_terreno (BTT) de los Juegos de Sydney, en una jornada en la que la italiana Paola_Pezzo, ganadora en Atlanta, revalidó su título olímpico, el único que se había disputado hasta la fecha.

Fullana entró en meta a 33 segundos de la campeona italiana, que cubrió los 35,7 kilómetros del recorrido olímpico en un tiempo de una hora, 49 minutos y 24 segundos, con una ventaja de 27 segundos sobre Barbara_Blatter, que regresará a Suiza con una medalla de plata.

La mallorquina, de 28 años, doble campeona del mundo de la especialidad (1999 y 2000), aspiraba al oro, pero la falta de un mayor desnivel en el circuito y una caída que sufrió en la cuarta vuelta tras chocar con Pezzo en un rocoso descenso la obligaron a conformarse con un bronce olímpico que, en cualquiera de los casos, pone broche a una sensacional temporada.

Fullana se situó pronto en los puestos de cabeza de una prueba en la que las competidoras dieron cinco vueltas a un circuito de 6,9 kilómetros - más un bucle llano de salida de 1.200 metros -, situado en la Fairfield_City_Farm, una granja en la que el ganado vacuno, ovino y porcino alterna con fauna autóctona como canguros, koalas o emús y que está a unos 30 kilómetros del Parque_Olímpico de Sydney.

Pero la primera en destacarse fue la suiza Blatter, que cruzó en cabeza las dos primeras vueltas de un recorrido cuyos diseñadores tuvieron especial cuidado en no dañar la flora y fauna del entorno, en unos Juegos cuya organización presume de ser la más ecológica de la historia.

Blatter abrió un hueco que fue de 17 segundos tras el segundo giro y que llegó a rozar el medio minuto en su amplitud máxima, pero a_falta_de dos kilómetros para completar la tercera vuelta, la ciclista balear enlazó con la suiza y la superó colocándose al_frente_de la prueba.

La autoridad del pedaleo de Fullana dejaba entrever la posibilidad de que la española redactase, efectivamente, la crónica de un oro anunciado : tras la tercera vuelta, la isleña lideraba con 14 segundos de ventaja sobre Blatter y 18 sobre Pezzo.

Pero en la cuarta, la italiana efectuó un sensacional despliegue de fuerza, superando a la helvética y conectando con la rueda trasera de Fullana, poco antes de adelantarla en una de las zonas más peligrosas del circuito, la "Dusty_Chute" ("caída polvorienta").

En un descenso con piso muy irregular, la italiana superó a Fullana tras chocar con ella y derribarla, en una maniobra que no estuvo bien vista por la delegación española, que quiso presentar una reclamación, algo que descarta el reglamento olímpico del "mountain-bike".

En la zona de meta se vivieron unos instantes no exentos de cierta tensión, pero los jueces, que, al_parecer, visionaron el vídeo del adelantamiento, no apreciaron la necesidad de alterar el desenlace de la prueba.

Fullana, que milita en el Specialized y cuyo entrenador es el ex ciclista holandés Gert_Jan_Theunisse, perdió un tiempo importantísimo tras su accidente; la italiana abrió hueco y Blatter enlazó desde atrás, superando a Marga en la quinta y última ronda.

La rusa Alla_Epyanova acabó cuarta en la prueba, a 1:21 y por delante de la canadiense Alison_Sydot, que cruzó la meta con un retraso de 2:54, en una prueba en la que la catalana Silvia_Rovira entró la decimocuarta, a 9:43.

Mañana se disputará en este mismo circuito la prueba masculina de esta disciplina, en la que se darán dos vueltas más que las dadas hoy por Fullana y sus rivales.

A la balear quizás le haya sabido a poco el bronce, pero tiene motivos suficientes para sonreír: Fullana pasará a la historia, entre otras cosas, por haber sido la primera mujer que logra una medalla olímpica para el ciclismo español.

Por favor, lea el siguiente texto periodístico y conteste las preguntas a continuación:

El jefe de la Oficina de Seguridad Nacional y ministro de la Presidencia polaca, Marek Siwiec, presentó hoy su dimisión de todos los cargos después de que varias cadenas de televisión locales transmitieran anoche un vídeo con imágenes en las que se burla del papa Juan Pablo II, imitando los gestos del Sumo Pontífice cuando llega a un país en peregrinación. "Presento mi dimisión, porque como político he perdido todo el prestigio que tenía y pido perdón a todos

aquellos a los que ofendí con mi irresponsable e irrespetuoso comportamiento", dijo el ministro Siwiec en un comunicado entregado a los medios.

El video fue grabado hace tres años, durante una visita a la ciudad de Kalisz del presidente de la República Aleksander Kwasniewski, al que acompañó el ministro Siwiec. Al descender del avión Siwiec hizo el gesto de la bendición y, cuando ya pisó tierra el presidente, según se escucha en la cinta, le dijo que se había olvidado de besar la tierra, cosa que su ministro hizo inmediatamente. El suceso tuvo lugar prácticamente en privado, ya que lo presenciaron solamente los acompañantes del presidente, sus escoltas y un grupo muy reducido de personalidades de la ciudad visitada. No obstante, la cinta con la grabación llegó a manos de Marian Krzaklewski, candidato de la derecha a la Presidencia y principal rival del actual jefe del estado, quien busca la reelección en los comicios fijados para el 8 de octubre.

[...] La burla ha despertado la ira de los polacos más identificados con el papa Wojtyla y ha causado malestar y desagrado incluso entre los partidarios y simpatizantes de Kwasniewski. La dimisión de Siwiec y sus ruegos de perdón por su broma de mal gusto no significarán el final del asunto: las imágenes que han provocado el revuelo han sido incorporadas a un anuncio electoral del candidato Krzaklewski.

Responda a las siguientes preguntas. Marque sólo una casilla. Si no tiene una ligera idea de cuál puede ser la respuesta correcta en alguna pregunta, déjela sin contestar.

1. ¿Quién se burla del Papa?
 - a. El Sumo Pontífice
 - b. El presidente de la República
 - c. El ministro
 - d. Los escoltas del presidente

2. ¿Quién besó la tierra durante la visita a la ciudad de Kalisz?
 - a. El presidente de la República
 - b. El ministro de la Presidencia polaca
 - c. Un candidato a la presidencia
 - d. El Papa

3. ¿Quién dimitió a causa de estos hechos?
 - a. Kwasniewski
 - b. Wojtyla
 - c. Krzaklewski
 - d. Siwiec

4. ¿Qué provocó la ira de los polacos más identificados con el Papa Wojtyla?
 - a. La dimisión del ministro
 - b. La dimisión del presidente
 - c. Que el ministro imitara al Papa durante la visita a Kalisz.
 - d. Que el presidente besara la tierra durante la visita a Kalisz.

5. ¿Quién incluyó el vídeo del suceso en un anuncio electoral?
 - a. El ministro Marek Siwiec
 - b. Marian Krzaklewski
 - c. El presidente Aleksander Kwasniewski
 - d. El jefe de la Oficina de Seguridad Nacional

A2

Por favor, lea el siguiente texto periodístico y conteste las preguntas a continuación:

La dirección de la Televisión de Catalunya (TV3) ha asegurado hoy que ha puesto todos los medios para que toda la audiencia española pueda seguir el Gran Premio de España de Fórmula Uno, así como el resto de carreras de esta temporada. El director de TV3, Lluís Oliva, ha explicado hoy que el canal catalán "ha alargado la mano todo lo que ha podido", con el objetivo de que el resto del estado español pueda ver el primer fin de semana de mayo la quinta prueba de Fórmula Uno, que se celebrará en el circuito de Montmeló, en Barcelona.

"No estamos poniendo ningún impedimento para que Televisión Española (TVE) retransmita la prueba, ni que acceda a todo el mundial. El año pasado ya compartimos todas las carreras e, incluso, no solicitamos oscurecer Catalunya para que la audiencia no viera por La 2 la carrera", ha añadido Oliva, quien ha recordado que el canal nacional no quiso transmitir los premios de Silverstone ni San Marino. "Hace cuatro años TV3 hizo una apuesta por la Fórmula Uno. Si hicimos una apuesta, ahora no vamos a hacer partícipes a terceros gratuitamente. El canal vasco (ETB-1) y el valenciano (Canal 9) son los únicos que fueron sensibles con nosotros, pero no TVE ", ha aclarado Oliva. Según el director del canal catalán, TVE " incumplió parte del contrato" suscrito la temporada pasada para que el canal nacional ofreciese por La 2 la temporada de Fórmula Uno.

Responda a las siguientes preguntas. Marque sólo una casilla. Si no tiene una ligera idea de cuál puede ser la respuesta correcta en alguna pregunta, déjela sin contestar.

6. ¿Qué cadena/s de televisión retransmitió el año pasado el mundial de Fórmula Uno en Cataluña?
 - e. La 2
 - f. TV3
 - g. ETB-1 y Canal 9
 - h. La 2 y TV3

7. ¿Con qué cadena/s de televisión muestra su desacuerdo el director de TV3, Lluís Oliva?
 - e. ETB-1 y Canal 9
 - f. TVE, ETB-1 y Canal 9
 - g. TVE
 - h. ETB-1

8. ¿Cuál/es fueron el/los premio/s que La 2 no emitió el año anterior?
 - e. España
 - f. España, Silverstone y San Marino
 - g. Silverstone y San Marino
 - h. Ninguno, emitió todos
